Marianne K. Morano Township Manager East Rockhill Township 1622 N. Ridge Road Perkasie, PA 18944

Re:

Ridge Run PFAS HSCA Site

East and West Rockhill Townships, Bucks County

Dear Ms. Marano:

The Department of Environmental Protection (DEP) would like to thank you for submitting comments during the public comment period concerning the Ridge Run PFAS HSCA Site. Public involvement is very important, and we consider all comments when deciding on a response.

Enclosed, please find a copy of the Statement of Decision (SOD) for the Site. DEP has selected Alternative 3, installation and maintenance of whole-house filtration systems with restrictions on the use of groundwater as the Interim Response at the Site. Responses to public comments can be found after the SOD.

Thank you for your interest in this matter. For additional updates on this Site, please visit our website, which can be found by searching: "PA DEP Ridge Run PFAS Site." https://www.dep.pa.gov/Citizens/MyWater/drinking_water/Perfluorinated%20Chemicals%20%E2%80%93PFOA%20and%20PFOS%20%E2%80%93%20in%20Pennsylvania/Pages/Ridge-Run-PFC-Site.aspx

Please do not hesitate to contact me if you have further questions. I can be reached by phone at 484.250.5722 or by email at cowade@pa.gov.

Sincerely,

Colin R. Wade

Environmental Protection Specialist

Bucks County Health Department (w/enclosures)

Re

COMMONWEALTH OF PENNSYLVANIA

Department of Environmental Protection Hazardous Sites Cleanup Program

Ridge Run PFAS HSCA Site
East and West Rockhill Townships, Bucks County

STATEMENT OF DECISION

The Commonwealth of Pennsylvania, Department of Environmental Protection (Department) files this statement of the basis and purpose for its decision in accordance with Section 506(e) of the Pennsylvania Hazardous Sites Cleanup Act, Act of October 18, 1988, P.L. 756, No. 108 (HSCA), 35 P.S. Section 6020.506(e).

The Department has selected the proposed Interim Response Alternative 3, Installation and Maintenance of Whole-House Filtration Systems (systems) with Restrictions on the Use of Groundwater, which is outlined in the Analysis of Alternatives and Proposed Response document to address the threats posed by exposure to per- and poly-fluorinated alkyl substance (PFAS) contamination above the United States Environmental Protection Agency's (EPA) published lifetime Health Advisory Limit (HAL) in residential privately-owned potable wells within the Ridge Run PFAS HSCA Site (the Site), located in East and West Rockhill Townships, Bucks County.

I. SITE INFORMATION

A. Site Location and Description

The Ridge Run PFAS HSCA Site (Site) is located along portions of Old Bethlehem Pike, Bethlehem Pike, Tabor Road, Hill Road and North Rockhill Road in East and West Rockhill Townships, Bucks County. The Site consists primarily of residential properties, with various recreational and several commercial and industrial properties. Recreational properties include community parks, a Veterans of Foreign Wars hall, and a state game land. Commercial properties include auto repair facilities, restaurants, a salon, a landscape products business, and a plant nursery. Also, within the Site are a church and school. Industrial properties include a quarry and an auto salvage yard.

B. Site History

In August 2016, the North Penn Water Authority conducted sampling for six types of PFAS in two public water supply wells in East Rockhill Township in accordance with the federal Unregulated Contaminant Monitoring Rule 3¹. Analysis of these samples detected combined concentrations of Perfluorooctane sulfonate (PFOS) and Perfluorooctanoic acid (PFOA) of 117

¹ Available at https://www.epa.gov/sites/production/files/2017-02/documents/ucmr3-data-summary-january-2017.pdf.

parts per trillion (ppt) and 70 ppt in these wells, both at or above the EPA HAL of 70 ppt for PFOS and PFOA.

After North Penn Water Authority's sampling activities, the Department sampled approximately 167 properties in its subsequent investigation of privately owned wells in the surrounding area. Of the 167 properties that the Department sampled, twelve (12) residential properties and one (1) commercial property have demonstrated sampling results with concentration levels above the HAL. The highest combined concentration of PFOS and PFOA detected was 16,360 ppt. No source area has yet been identified. The Department continues to sample properties affected by PFOS and PFOA contamination to monitor concentration levels at the Site. The Department has also been providing bottled water to the residential properties impacted above the HAL.

C. Release of Hazardous Substances and Contaminants

The compounds identified above are considered "contaminants" as that term is defined by Section 103 of HSCA, 35 P.S. § 6021.103, and Section 9601 of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), 42 U.S. Code § 9601. Exposure to concentrations of PFOS and PFOA above the HAL pose a threat to human health when ingested in water.

Health effects associated with long-term exposure to these chemicals may include developmental delays, decreased function of the liver, damage to the immune system and increased risk of certain cancers.

PFAS are not found naturally in the environment. Of the PFAS chemicals, PFOA and PFOS have been the most extensively produced and studied. They have been used to make cookware, carpets, clothing, fabrics for furniture, paper packaging for food, and other materials that are resistant to water, grease, or stains. They are also used in firefighting foams and in a number of industrial processes.

II. RESPONSE CATEGORY

The selected response is an Interim Response, which is defined in Section 103 of HSCA, 35 P.S. § 6020.103, as a response which does not exceed 12 months in duration or \$2,000,000 in cost, except under certain circumstances.

III. CLEANUP STANDARDS

The selected response is not a final remedial response pursuant to Section 504 of HSCA, 35 P.S. § 6020.504.

Additional response actions may be needed to achieve a complete and final cleanup for the Site.

IV. APPLICABLE, RELEVANT and APPROPRIATE REQUIREMENTS (ARARs)

The following standards, requirements, criteria or limitations are legally applicable, or relevant and appropriate under the circumstances presented by the Site.

A. ARARs

Hazardous Sites Cleanup Act, Act of October 18, 1988, P.L. 756, No. 108, as amended, 35 P.S. §§ 6020.101 et seq.

- Gives the Department the authority to perform investigations, initiate cleanups, and provide replacements for contaminated water supplies.
- Establishes a fund to cover the costs of such activities.
- Provides administrative procedures for conducting response actions.
- Defines a "contaminant" and "hazardous substance" as any substance defined as such by CERCLA.

Comprehensive Environmental Response, Compensation and Liability Act of 1980, 42 U.S. Code §§ 9601 et seq.

Defines a "contaminant" as any element, substance, compound, or mixture, which
when released to the environment and upon ingestion, may reasonably be
anticipated to cause disease, cancer and other harm to humans and other
organisms.

Land Recycling and Environmental Remediation Standards Act, Act of May 19, 1995, P.L. 4, 35 P.S. §§ 6026.101 *et seq.*, and the regulations promulgated thereunder at 25 Pa. Code Chapter 250.

- Provides that, for regulated substances where no Maximum Contaminant Level (MCL) has been established by the Department or the EPA, the Medium-Specific Concentrations for groundwater are the Lifetime HAL.
- Provides remedial standards to be considered as applicable, relevant and appropriate requirements under CERCLA and HSCA.

Pennsylvania Safe Drinking Water Act, Act of May 1, 1984, P.L. 206, No. 43, as amended, 35 P.S. §§ 721.1 et seq., and the regulations promulgated thereunder at 25 Pa. Code Chapter 109.

- Establishes a state program to oversee the provision of safe drinking water to the public.
- Sets forth drinking water quality standards and provides requirements for public water systems, including permit design, construction, source quality, and siting requirements.

Uniform Environmental Covenants Act, Act of December 18, 2007, P.L. 450, No. 68, 27 Pa. C.S. §§ 6501 *et seq.* ("UECA"), and the regulations promulgated thereunder at 25 Pa. Code Chapter 253.

• Provides a standardized process for creating, documenting and assuring the enforceability of activity and use limitations on contaminated sites.

• Requires an environmental covenant whenever an engineering or institutional control is used to demonstrate the attainment of an Act 2 remediation standard for any cleanup conducted under an applicable Pennsylvania environmental law.

B. TO BE CONSIDERED.

In addition to the ARARS listed above, the following documents are relevant to the response actions proposed herein, though they do not create any statutory or regulatory obligations.

Standard Operating Procedure for the Hazardous Sites Cleanup Program, HSCA Handbook, Division of Site Remediation, Bureau of Environmental Cleanup and Brownfields, January 2013.

Guidance for Commonwealth-Funded Water Supply Response Actions, November 21, 2015, Department of Environmental Protection, Bureau of Environmental Cleanup and Brownfields, document number 262-5800-001.

- Outlines implementation of Commonwealth-funded water supply responses, including procedures for providing temporary or permanent response actions for impacted private water supplies.
- Details specific work related to response actions that may be financed via the HSCA fund.
- Explains operation and maintenance duties of response actions, including the appropriate parties that should conduct such activities.
- Describes the use of institutional controls as part of the response action process.

V. ANALYSIS OF ALTERNATIVES

ALTERNATIVE 1: No Action

Description of the Alternative:

The no further action alternative serves as a baseline to compare against other proposed response action options. Under this alternative the Department would take no further action and would not continue providing bottled water to affected residents.

Protection of Human Health and Environment:

This alternative would not eliminate the ingestion exposure pathway for PFOS and PFOA above the HAL.

Compliance with ARARs:

This alternative would not comply with ARARs. The public would be exposed to concentrations of PFOS and PFOA in the groundwater and drinking water above the HAL established by the EPA.

Feasibility, Effectiveness, Implementability and Permanence:

This alternative would be feasible and implementable because no action is being taken but would not be effective in addressing the health threats to the public.

Cost Effectiveness:

There is no cost associated with this alternative.

Alternative 2. Continued Delivery of Bottled Water (for a 12-month period) with Restrictions on the Use of Groundwater

Description of Alternative:

Under this alternative, the Department would continue to supply bottled water to the residential properties in the Site that have untreated privately owned potable wells with concentrations of PFOS and PFOA above the HAL. The commercial property would not be included in this alternative. Bottled water would be supplied for a 12-month period. The Department would sample the wells over this period to determine if PFOS and PFOA remain above the HAL. After 12 months, residents would be responsible for securing their own potable water. The Department would sample the residential properties for a year after the completion of this alternative as part of its investigation of the Site.

Pursuant to Section 512 of HSCA, 35 P.S. § 6020.512, and Section 6517(a)(2) of UECA, 27 Pa.C.S. § 6517(a)(2), the Department would ensure that future property owners are aware of the contamination and that future exposure to PFOS and PFOA at any property is eliminated by requiring that a limitation on groundwater usage be included in an environmental covenant recorded at the local recorder of deeds.

Protection of Human Health and Environment:

This alternative would effectively eliminate the ingestion exposure pathway for PFOS and PFOA above the HAL.

Compliance with ARARs:

This alternative would comply with ARARs as the bottled water that the Department uses to supply affected residential properties does not have PFOS and PFOA above the HAL. The Department sampled the bottled water that is being supplied to verify that it does not have PFOS and PFOA above the HAL.

Feasibility, Effectiveness, Implementability and Permanence:

This alternative is not considered a permanent solution because it would not allow the existing residential privately owned potable wells at the Site to be used as potable wells for an

undetermined amount of time. Additionally, this alternative may be difficult to implement in times of inclement weather.

Cost Effectiveness:

The estimated cost of continuing to provide bottled water to affected residential properties above the HAL for 12 months is approximately \$6,500.

Alternative 3. Installation and Maintenance of Whole-House Filtration Systems with Restrictions on the Use of Groundwater

Description of Alternative:

Under this alternative, the Department would install and maintain Whole-House Filtration Systems in the form of point of entry treatment (POET) systems. These systems would be placed in homes in the Site that have untreated privately owned potable wells with concentrations of PFOS and PFOA above the HAL. The Department would sample the systems over an initial 12-month period to determine if the filters are operating properly. The Department would continue to provide bottled water during this period until the systems have demonstrated that they are reducing PFOS and PFOA concentrations to below the HAL. After that 12-month period, the responsibility for maintaining the systems would be turned over to homeowners. The commercial property would not be included in this alternative.

Pursuant to Section 512 of HSCA, 35 P.S. § 6020.512, and Section 6517(a)(2) of UECA, 27 Pa.C.S. § 6517(a)(2), the Department would ensure that future property owners are aware of the contamination and that future exposure to PFOS and PFOA at any property is eliminated by requiring that a limitation on groundwater usage be included in an environmental covenant recorded at the local recorder of deeds.

Protection of Human Health and the Environment:

This alternative would effectively eliminate the exposure pathways and, as a result, eliminate exposure to concentrations of PFOS and PFOA in the groundwater above the HAL. This alternative would also have the benefit of potentially providing control of local groundwater flow direction and preventing further spread of the PFOS and PFOA in groundwater at the Site via the continued pumping of existing wells.

Compliance with ARARs:

This alternative would comply with ARARs because the systems would reduce PFOS and PFOA concentrations to below the HAL.

Feasibility, Effectiveness, Implementability and Permanence:

This alternative is considered permanent provided that the systems are properly maintained and monitored. This alternative does require ongoing monitoring and maintenance costs for the property owners in order to ensure the systems are effective in eliminating exposure to

Ridge Run PFAS HSCA Site Statement of Decision

concentrations of PFOS and PFOA in groundwater above the HAL. This alternative also allows for the Department to quickly and efficiently expand and implement it for a relatively low cost should additional properties be identified in the future as affected by PFOS and PFOA contamination as the investigation continues. Relative to Alternative 4, this alternative can be more quickly implemented.

Cost Effectiveness:

The costs associated with this alternative include installation, sampling and maintenance of systems at 12 impacted residential properties over a 12-month period. The Department will continue to provide bottled water until the systems demonstrate they are reducing PFOS and PFOA to below the HAL

The systems will require periodic maintenance for the systems to continuously and effectively treat the water. Maintenance or issues related to the systems may arise in the initial 12-month period following installation, which the Department would cover.

Overall, the total cost for Alternative 3 is estimated at \$102,860, making it a cost-effective alternative.

Alternative 4. Extension of an Existing Public Water Line, with Restrictions on the Use of Groundwater

Description of Alternative:

Under this alternative, the Department would fund the connection of affected and threatened residential properties to an existing water line in the Site area. The Department would fund: 1) any necessary construction of an extension of existing water line mains, 2) the lateral connections from the main to the affected properties, 3) the connection of the laterals to the existing buildings' plumbing, 4) the repairs to all road surfaces or properties disturbed by the water line construction, and 5) the abandonment of residential privately owned potable wells. Groundwater usage would be restricted by a municipal ordinance to ensure residents cannot be exposed to PFOS and PFOA above the HAL. Such an ordinance would require all residential properties with privately owned potable wells with concentrations of PFOS and PFOA above the HAL to abandon those wells and connect to public water. The commercial property would not be included in this alternative.

Protection of Human Health and the Environment:

This alternative would effectively eliminate the exposure pathways for PFOS and PFOA above the HAL.

Compliance with ARARs:

This alternative would comply with ARARs. It would eliminate the exposure to PFOS and PFOA above the HAL in the groundwater. The utility providing the public water would be required to provide their customers with potable water below the HAL for PFOS and PFOA.

Feasibility, Effectiveness, Implementability and Permanence:

This alternative is effective at eliminating exposure to PFOS and PFOA among the currently identified affected properties and would be permanent in nature. This alternative is not as quickly implemented as Alternative 3, because it would involve a long period of construction. In addition, the Department's investigation is ongoing and as it progresses, the Department may identify additional properties where exposure must be addressed. Given the current uncertainties in groundwater conditions and the complex area geology of the Site, this alternative is less feasible than Alternative 3, because the line cannot be extended quickly or efficiently to address new exposures, if discovered. Finally, this alternative requires that included residential properties abandon their groundwater wells, the process of which could affect groundwater flow and result in the further spread of PFOS and PFOA.

Cost Effectiveness:

The estimated cost for Alternative 4 is over \$2,000,000. The Department does not consider this a cost-effective alternative since the groundwater conditions at the Site may continue to change and additional properties may be affected in the future. This alternative is cost-prohibitive because the entirety of the Site would need to be connected to the waterline to guarantee that no additional properties will be exposed to the groundwater with concentrations of PFOS and PFOA above the HAL.

VI. SELECTED RESPONSE

The Department has determined, based upon the information contained in this document and the Administrative Record, that an Interim Response action is justified at the Site in accordance with Section 505(b) of HSCA, 35 P.S. § 6020.505(b).

The Department has selected Alternative 3, installation and maintenance of whole-house filtration systems with restrictions on the use of groundwater (Selected Response), as an Interim Response at the Ridge Run PFAS HSCA Site. The Selected Response is effective in mitigating threats to public health and is cost effective.

The Selected Response, Alternative 3, affords substantially more protection to human health than Alternatives 1 and 2, and is as protective as Alternative 4 because it eliminates exposure to the contaminants in groundwater. The Selected Response abates the threat to human health from ingestion of water containing PFOS and PFOA above the HAL while allowing for the continued investigation of the Site.

The Department received comments from several residents, the Perkasie Regional Water Authority, and East Rockhill and West Rockhill Townships in support of Alternative 4. As discussed above, the widespread spatial area of the Site and remaining uncertainties regarding the long-term groundwater flow and number of properties affected makes the implementation of Alternative 4 neither feasible nor cost-effective at this time.

The Selected Alternative provides flexibility so that additional systems may be installed if subsequent sampling identifies properties where concentrations of PFOS and PFOA in residential privately owned potable wells exceed the HAL.

The Department will continue to monitor the concentrations of PFOS and PFOA at the residential properties where the systems are installed for at least one year after the completion of the Interim Response period as part of its ongoing investigation of the Site.

VII. MAJOR CHANGES FROM PROPOSED RESPONSE

In the Analysis of Alternatives, the systems were described specifically as carbon filtration systems. The Department received multiple comments during the public comment period questioning the efficacy and protectiveness of the systems to be installed under the Selected Response. To address these concerns, the Department will evaluate which filtration systems will be most effective at the Site and install those systems. In addition, to ensure protectiveness of the Selected Response, Alternative 3 was changed to include the provision of bottled water to the residential properties during the Interim Response period until sampling results demonstrate the systems are removing PFOS and PFOA below the HAL.

The Analysis of Alternatives indicated that the Department would perform operation and maintenance activities of the filtration systems installed as part of the response action for a duration of 12-months. The Department received multiple comments during the public comment period requesting that this duration be extended. In response to these comments, at the end of this 12-month period, the Department will evaluate whether any of the circumstances exist that would allow an interim response to exceed 12 months in duration under the HSCA definition of "interim response" and, if so, whether the 12-month period should be extended accordingly. At the end of the 12-month period, to evaluate the "interim response" the Department will utilize evaluation criteria that is consistent with the criteria established in the applicable rules and regulations, which includes effectiveness, community acceptance, cost effectiveness, human health protectiveness, and ease in implementation.

The Department has added UECA as an ARAR as a mechanism to ensure the protectiveness of the Selected Response through the use of environmental covenants to ensure maintenance of the systems, continued post-treatment well water sampling, and acknowledgment and prohibition on the use of groundwater on properties with concentrations of PFOS and PFOA above the HAL.

VIII. RESPONSE TO PUBLIC COMMENTS

The Department's response to public comments concerning the selection of this response action is filed in the administrative record.

FOR THE COMMONWEALTH OF PENNSYLVANIA DEPARTMENT OF ENVIRONMENTAL PROTECTION

Patrick L. Patterson, Regional Director

Southeast Region Office

DEPARTMENT OF ENVIRONMENTAL PROTECTION

Hazardous Sites Cleanup Program

RESPONSE TO COMMENTS

Ridge Run PFAS HSCA Site

April 18, 2019

Notice of the establishment of an Administrative Record concerning the proposal of the Interim Response at the Ridge Run PFAS HSCA Site (Site) was published in the Pennsylvania Bulletin on June 2, 2018, and in the Bucks County Courier Times on June 3, 2018. The Administrative Record was available for public review at the East Rockhill Township Building, the West Rockhill Township Building, and the Pennsylvania Department of Environmental Protection Southeast Regional Office in Norristown. The Department accepted comments on the Administrative Record between June 2, 2018 and August 31, 2018 and conducted a public hearing on July 11, 2018, at the West Rockhill Township Building. During the hearing, the Department accepted oral comments on the Administrative Record. The Department has compiled all comments, both oral and written, received during the comment period. Oral comments have been excerpted from the public hearing transcript and a complete transcript of the oral comments is available for review at the Department's Southeast Regional Office in Norristown.

Oral Commenters:

- 1.) Tracy Carluccio
- 2.) Kelly Jameson
- 3.) Angela Goodwin

- 4.) Jim Pascale
- 5.) Sandra Moyer
- 6.) Gerald Moyer

- 7.) Jennine Gravel
- 8.) Dave Watt
- 9.) Sue Furlong

Written Commenters:

- 1.) Kelly & Jerry Jameson
- 2.) Jodi Cutaiar
- 3.) Jessica Conrad

- 4.) Angela Goodwin
- 5.) Tracy Carluccio
- 6.) Sheri D'Ginto
- 7.) West Rockhill Township 8.) Chris LaBelle
- 9.) Andi Stephenson
- 10.) East Rockhill Township 11.) Emily Geib
- 12.) Ryan Gottshall

- 13.) Kimberly Gottshall
- 14.) Perkasie Regional Water Authority
- 15.) Gerry Moyer
- 16.) Peter McClennen

For each comment, the name of the commenter, and the Department's response are listed below:

Oral Commenter #1: Tracy Carluccio. Oral Comments transcribed on pages 27 - 31 of the hearing transcript.

Oral Comment 1-1:

"My name is Tracy Carluccio. I'm Deputy Director of Delaware River Keeper Network. First, we do not agree that applying the U.S. EPA health advisory level of 70 parts per trillion is reasonable and we think that using it actually can mask the amount of contamination that exists. I know we're not supposed to address this, but I think it is important to note that in June the ATSDR released minimum

risk levels that reduce the level at which no harm can be expected to approximately 7 parts per trillion for PEOS and 11 for PFOA. PFAS is highly toxic and linked to devastating disease such as cancer and developmental defects in children and infants, and even miniscule concentrations can have adverse health effects, particularly when you consider that it builds up in the blood and is not easily extruded by the body.

So we're also aware that many states are considering lower levels. New Jersey, for instance, is going to adopt mandatory maximum contaminant levels of 14 parts per trillion for PFOA and 13 parts per trillion for PFOS. And Delaware River Keeper Network, my organization, filed a formal petition with Pennsylvania's Environmental Quality Board last year asking that they set an MCL for PFOA of one part per trillion and no greater than six parts per trillion based on the most recent science. The EOB did accept that petition and they' re in the process of considering setting an MCL. We recently brought to the EQB's attention, by the way, that New Jersey did recommend this MCL for PFOS of 13 parts per trillion, and we submitted Delaware River Keeper Network's expert commissioned report that recommends 5 parts per trillion for PFOS. Based on the most recent science, the trigger for remediation and water replacement for people should either be a non—detect on no greater than 5 for PFOS or 1 to 6 PPT for PFOA. This substantially changes DEP's evaluation, and it affects the costs and how it's spread out and how many people it's spread out over, especially if PFAS is detected in more wells. Your summary of the groundwater sampling does show that there were detections in many more than 12 wells, and if the action level moves downwards, then more people will share will be affected either in bearing the cost of full house system maintenance after the installation period of one year or for the community to bring in water a water system. So we 're very concerned that the action that's being proposed is not going to address the problem or be protective enough."

Response to Oral Comment 1-1: The Department appreciates your comment. The purpose of the Interim Response is to provide an alternative source of drinking water for residential potable wells where concentrations of PFOS and PFOA combined or separately exceed the Lifetime Health Advisory Level (HAL) of 70 parts per trillion for PFOS and PFOA, separately, or combined.

Pennsylvania's Environmental Quality Board has not proposed a State Maximum Contaminant Level (MCL) before issuance of the Statement of Decision. If a State or Federal MCL is issued for PFOS or PFOA that is different from the HAL, DEP will reevaluate the Site, and will take action as necessary and appropriate.

Oral Comment 1-2:

"My organization supports alternative four, the piping in of public contaminant free water to provide the protection that is needed. Extending the public water system could be coupled with alternative three by the or by the use of bottled water until the pipe system is operating."

Response to Oral Comment 1-2: At this time, uncertainties in groundwater conditions in the area and complex area geology make Alternative 4 less feasible than Alternative 3, as the waterline might have to be extended significantly over time. In addition, Alternative 4 is not as quickly implemented as Alternative 3, would involve a long period of construction, and could allow the further spread of PFOS and PFOA if existing residential privately-owned wells are abandoned, possibly changing groundwater flow. Moreover, the estimated cost for Alternative 4 is over \$2,000,000. The Department does not consider this a cost-effective alternative since the groundwater conditions at the Site may continue to change and additional properties may be affected in the future. Alternative 4 is cost-prohibitive because the entirety of the Site area would need to be connected to the waterline to

guarantee no additional properties will be exposed to the groundwater with concentrations of PFOS and PFOA above the HAL.

The Department has selected Alternative 3, the installation of Whole-house Filtration Systems with Restrictions on the Use of Groundwater as the Interim Response at the Site. The Selected Response includes sampling of the systems to ensure they are reducing PFOS and PFOA to below the HAL and the provision of bottled water to the residential properties where PFOS or PFOA concentrations exceed the HAL until the systems demonstrate their effectiveness.

Oral Comment 1-3:

"However, alternative three's condition of turning the systems over to the homeowners after one year is unacceptable and unfair. Extending the public water system and using bottled water or whole house filters in the meantime or in those outlying wells will provide immediate long term relief for an already impacted community."

Response to Oral Comment 1-3: Under the Hazardous Sites Cleanup Act (HSCA) definition of "interim response," an Interim Response may not exceed twelve months in duration except in certain limited circumstances. The maintenance period is limited to twelve months to comply with this requirement. In response to these comments, at the end of this twelve-month period, the Department will evaluate whether any of the circumstances exist that would allow an interim response to exceed twelve months in duration under the HSCA definition of "interim response" and, if so, whether the twelve-month period should be extended accordingly.

In addition, for properties at the Site where PFOS or PFOA concentrations exceed the HAL, the Department has determined that an institutional control in the form of restrictions on the use of such groundwater is necessary to eliminate the long-term potential risk of exposure to groundwater contamination. Consequently, pursuant to the Uniform Environmental Covenant Act (UECA), the Department intends to use environmental covenants to effectuate such institutional controls. In addition, in order to provide the level of treatment necessary to reduce the levels of contaminants of concern to the HAL or below, the filtration systems require regular monitoring and maintenance. The Department intends to use environmental covenants to ensure that the affected property owners continue to monitor and maintain the filtration systems so that they continue to provide safe drinking water. The environmental covenants will also place future owners of the affected properties on notice of the applicable requirements.

Oral Comment 1-4:

Regardless of the solution, my organization feels it's vitally important that the environmental cleanup of the pollution commences in tandem with the provision of clean drinking water to the community, and that the source be found and the solution on be coupled with finding that responsible party that could have the pockets that would pay for this, rather than the taxpayer or the homeowner."

Response to Oral Comment 1-4: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-1 regarding the purpose of the Interim Response. Further response actions may be proposed as necessary to address other environmental media at the Site. No

Potentially Responsible Parties have been identified at this time. The Department's investigation of the Site is ongoing.

<u>Oral Commenter #2:</u> Kelly Jameson. Oral Comments transcribed on pages 31 - 33 of the hearing transcript:

Oral Comment 2-1:

"Hi. I'm Kelly Jameson. I live 6 Highpoint Circle, one of the wells, public wells, that were shuttered and switched to Perkasie. For 20—plus years, citizens in our neighborhood have drinking this poisoned water. Within the past eight years, we've neighbors die from colon and breast cancers, young child taken by leukemia, classmates of my child suffering from Tourette's and our own child stricken with autoimmune disorders, inflammatory bowel disease and PANDA, which is Pediatric Autoimmune Neuropsychiatric Disorders Associated with streptococcal infection. The EPA has connected these diseases to PFOA and PFOS exposure. However, your response does not include PFOA, PFOS blood testing or monitoring for u. For 20 years, we drank this fouled water. It's irresponsible to tell us everything is okay now that you've closed the poison wells and switched our water supply. Like the people in Warrington who drank the PFC tank took water from the naval base, we need blood testing and annual health monitoring. We need to be ensured PF PFOS, P you know what I 'm saying PFC s isn't hiding in our hot water tank sediment and continuing to poison us. So I request testing of our water tank sediment as previously requested in an unanswered e—mail to EPA. If found to be positive for P FOS, PFOA, the water tank should be replaced."

Response to Oral Comment 2-1: The Department appreciates your comment. This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-1 regarding the purpose of the Interim Response. The public supply wells that exceeded the HAL were shut down in 2016.

Oral Comment 2-2:

"Number two, PFOA, PFOS blood testing for those of who drank water supply water supplied by tainted wells."

Response to Oral Comment 2-2: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-1 regarding the purpose of the Interim Response. Health concerns regarding exposure to PFOS and PFOA may be directed to Anil Nair, PhD, Director, Division of Environmental Health Epidemiology, Pennsylvania Department of Health and/or your physician.

Oral Comment 2-3:

"Three, ongoing health monitoring for those victims found with elevated blood levels with PFOS, PFOA."

Response to Oral Comment 2-2: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-1 regarding the purpose of the Interim Response. Please see the Department's Response to Oral Comment 2-2 regarding to whom health concerns regarding exposure to PFOS and PFOA may be directed.

<u>Oral Commenter #3:</u> Angela Goodwin. Oral Comments transcribed on pages 33 - 36 of the hearing transcript.

Oral Comment 3-1:

"Angela Goodwin, Tabor Road. Couple of things. I 'm going what I 'm speaking about is I'm taking care of myself and my family. You guys are taking care of yourself and your company. Right? As West Rock hill is taking care of themselves and Bergey's is taking care of themselves as well. Nobody's taking care of us. One of the things that you put up there was about the cost of the filters and what it's going to cost them. How about the cost of what we just lost in our home and the real estate value and our properties? What about the cost of, you know, our health and our family's health?"

Response to Oral Comment 3-1: The Department appreciates your comment. This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-1 regarding the purpose of the Interim Response. When taking an action under HSCA, the costs the Department can consider are to limited to those associated with actions to assess, prevent, minimize, or mitigate damage to the public health. For the Selected Response, the costs are for the installation of the whole-house filtration systems, the initial monitoring and maintenance of those systems, and the provision of bottled water until the systems demonstrate their effectiveness.

Oral Comment 3-2:

"We've asked, like I said, for well water to be for soil samples to be done. That hasn't been done. Now, wells contaminated. The basin, retention basin, that 's next to our house or behind our house doesn't drain down to the stream or didn't at that point in time. I have proof here. I got a hold of the conservation district after it filled for a year and a half and the 35 conservation district has been at our house. It used to drain on the property, the vacant lot next to us, which then ran down the road, our road, that we maintain and then down onto another the same neighbor's property across the street. It never made it down to that stream. You guys are testing streams and everything else or they tested streams where it never made it to. It wasn't until I had the retention basin fixed with the conservation district 's help that it 's been actually put out to where it's supposed to be."

Response to Oral Comment 3-2: Please see the Department's Response to Oral Comment 1-1 regarding the purpose of the Interim Response. The Department's investigation of the Site is ongoing and includes the sampling of other environmental media.

Oral Comment 3-3:

"The other thing I wanted to mention was you keep on saying about having a you're putting in well systems to test. Now, how do we know that that them well systems that you're going to monitor aren't going to change the way the water flow goes? Or how about if that development goes in across from where we live? Does it change the way the water goes? Does it make everything worse?"

Response to Oral Comment 3-3: The Department's investigation of the Site is ongoing and will determine groundwater flow direction. The proper installation and construction of monitoring wells at the Site is not expected to affect the direction of groundwater at the Site.

Oral Comment 3-4:

The filters that go into our home, I have a higher level than, you know, somebody else down the street. That could cost me even more money than what somebody it might cost somebody else. The our filter could we could get it tested now and then a couple months later, you know, it's bad.

Response to Comment 3-4: Please see the Department's Response to Oral Comment 1-3 regarding sampling and maintenance of the systems.

Oral Comment 3-5:

"The other thing I wanted to know is how come Bergeyrs - a letter was sent to them in January or February, but yet they didn't respond. We sent another one in May. Have they ever responded? Have they ever complied? From what I can see from old newspaper articles, nobody's responded, nobody's cared about the residents that lived here, not Bergeyrs, not the township, nobody."

Response to Oral Comment 3-5: The Department received a response from Bergey's Realty Company to the Department's Request for Information in June 2018.

Oral Commenter #4: Jim Pascale. Oral Comments transcribed on pages 36 - 39 of the hearing transcript:

Oral Comment 4-1:

"I think what when I look at the report and I see the concentration effort on just the red dots, in light of the comment that was made earlier regarding the changing of standards, I mean, they're changing rapidly. We're talking about 60 parts per million if that's the proper technology, it's ridiculous. So I think we need to take our head out of the sand and recognize that we need to have a solution that provides for a more realistic standard, which I 'm hearing now is 7,11. And that will take into account lots of property. So that's point number one. I think we're looking we're missing the target. We're missing the target by putting our head in the sand and saying this is the standard, this is what we got to live with, but everyone at that table you know that's a lower number, but you don't live where we live."

Response to Oral Comment 4-1: The Department appreciates your comment. This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-1 regarding regulatory standards for PFOS and PFOA and their application to the Interim Response.

Oral Comment 4-2:

"Comment number two, the cost analysis is extremely faulty and emphasizes DEP resources and how much DEP has to pay. When you look at this, what about all the homeowner responsibilities here? Testing costs a fortune. So it's skewed to come up with give everybody a a free system if they put a restriction on their deed.

So we're planning to meet a standard that is way too high and over time it 's going to be outdated quickly. So let's be smart. Let's not be stupid. Cost analysis. Let's talk about the total cost because clearly that's not you compare the apples and oranges, if you look at putting in a water system, which I would recommend, you're actually resolving a problem. You're giving clean water to the residents and

the residents I'm sure realized that they don't ever have to worry if they have the Perkasie Water Authority taking care of them and they' re going to get clean water. I'm not going to get it. That's a value added to their property and something that I think some of the property owners would be find would be to their best interest. That's a solution."

Response to Oral Comment 4-2: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 3-1 regarding the purpose of the Interim Response and the valuation of real estate.

Oral Comment 4-3:

"The tests. looked at the test sites before. I guess DEP based there was a contaminated well so this is ground zero, contaminated well. we're going to do a one an arbitrary. I don't know what one mile. I wasn't in that area, perimeter around the well. Well, now we're finding out it's really shifting over to Bethlehem Pike, and this should be an interim report because I think a new line needs to be drawn. If we have a hot spot, you're probably you know, you may be leaving other areas out. I would I would go to ground zero in the area by Bergey's and and see what the test results are."

Response to Oral Comment 4-3: The Department's initial sampling did focus on sampling all residential wells within a one-mile radius from the public supply wells that were taken offline. However, the Department has expanded the area of investigation multiple times based on its investigation. The Department is continuing its investigation of the Site and will continue to assess the need for expanding the area of investigation.

Oral Comment 4-4:

"And the last thing is this mandatory covenant. I'm offended. I don't know how the homeowners feel about it. You're telling me you're going to give them a cookie. You're going to give them a \$2,000 water treatment system, but you got to you're actually going to ask these residents to sign on a document that will be on a deed that will make their properties not very desirable for people to buy? Why don't you just take the high road? These are not bad people. These are good people. So let them have their system. Believe me, they want to maintain it. They don't want the contamination. We don't they don't need a gun to their put to their head by the DEP to tell them they need to change their filters if you go that route, which I wouldn't recommend."

Response to Oral Comment 4-4: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-3 regarding the purpose of the institutional controls.

Oral Commenter #5: Sandra Moyer. Oral Comments transcribed on pages 40 - 41 of the hearing transcript:

Oral Comment 5-1:

"One thing I was curious about, I never we were never contacted by our West Rockhill anything about this well business. In fact, I didn't even know this meeting was taking place tonight until we were interviewed by a wonderful reporter who said now, we were in the newspaper this past week, pictures,

blah, blah, blah, and that's the first I knew that this was even going to be addressed tonight, which is a little discouraging."

Response to Oral Comment 5-1: The Department appreciates your comment. Notice of the opening of the Administrative Record and of the time and place of the public hearing was published in the June 2, 2018 issue of the *Pennsylvania Bulletin* and the June 3, 2018 edition of the *Bucks County Courier Times*. In addition, the Department has created a public website for this Site: <a href="https://www.dep.pa.gov/Citizens/MyWater/drinking_water/Perfluorinated%20Chemicals%20%E2%80%93PFOA%20and%20PFOS%20%E2%80%93%20in%20Pennsylvania/Pages/Ridge-Run-PFC-Site.aspx

This website can also be found by searching: "PA DEP Ridge Run PFAS Site."

Oral Comment 5-2:

"People have mentioned about the property value. Basically, I feel like our house can't even be sold now and I kind of would like to look into downsizing now."

Response to Oral Comment 5-2: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 3-1 regarding the purpose of the Interim Response and the valuation of real estate.

Oral Comment 5-3:

I am a cancer survivor, I hope six surgeries just last year, breast cancer, and, again, my father just passed away who lived here for many years, from lung cancer, you know. And another lady passed away a few years ago. My son—in—law didn't even mention this. She became very concerned about her health over the 41 years and she started drinking water like crazy. she died from this horrible cancer that ended up in her neck.

Response to Oral Comment 5-3: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 2-2 regarding to whom health concerns regarding exposure to PFOS and PFOA may be directed.

Oral Comment 5-4:

"So I just I feel like bring us public water. It would be a sure fix. this is - this is crap. I mean, I appreciate you want to do something, but it's not -I don't feel safe. I will never want to drink that water again after all my surgeries and what I I've been through already. Thank you."

Response to Oral Comment 5-4: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-2 for information regarding why Alternative 3 was selected over Alternative 4 and how the Department will ensure the protectiveness of the Selected Response.

Oral Commenter #6: Gerald Moyer. Transcribed on pages 41 - 44 of the hearing transcript.

Oral Comment 6-1:

"You talked about I'm just concerned you talked about cost effectiveness effectiveness for DEP. Okay? But you're not looking at our cost effectiveness. I mean, you did a study there three to five years, but you want to say we're responsible for one year we're we're responsible after one year, which I totally think that's insufficient."

Response to Oral Comment 6-1: The Department appreciates your comment. This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-3 for a discussion of how the time period of the Interim Response was established.

Oral Comment 6-2:

"It just doesn't add up. The carbonization filters, you know, there's I don't think there's been enough study, I mean, because we 've only known more or less about this PFOA last, what, two, three, four year. I mean, what kind of study has been for these to be effective? This is what I 'm concerned about, especially when you face we've been drinking this water."

Response to Oral Comment 6-2: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-2 for information regarding how the Department will ensure the protectiveness of the Selected Response.

Oral Comment 6-3:

"So, you know, when you're in the shower, you open your mouth it just feels good to, you know, have you know, refresh. And it's easily absorbed by the mouth, you know, and it just makes you think, well, you know, where'd this come from? You know, because I 've always been healthy and then I face health issues because of that. I had a heart valve replaced and that came from the endocarditis that I had contracted."

Response to Oral Comment 6-3: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 2-2 regarding to whom health concerns regarding exposure to PFOS and PFOA may be directed.

Oral Comment 6-4:

"So I really wanted to - to say that cost effectiveness is not looked at for the - for the residences . And I just think that one year and I believe I was told that that 's the policy at the DEP is just insufficient. The other part of that is then the homeowner is also responsible for the upkeep of the filter. Okay. Understandable, but also for water testing. And to test this - this PFOS it's not a normal water test. So there you go. You know, you're I understand as a homeowner the well is your responsibility and you get a water test, yeah, we 've had water tests over the years, but never tested for this . Now all of a sudden we re faced with this and that's another expense."

Response to Oral Comment 6-4: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-3 regarding sampling and maintenance of the systems.

Oral Comment 6-5:

"The other thing is that we' re not really talking about blood testing because I think blood to really get down and dirty with this, to understand what 's happening here is we need to do more research on what - what it' really doing to the effectiveness?"

Response to Oral Comment 6-5: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 2-2 regarding blooding testing.

Oral Commenter #7: Jeannine Gravel. Transcribed on pages 44 - 45 of the hearing transcript.

Oral Comment 7-1:

"I just wondered if the DEP would consider hiring a professional hydrologist or multiple hydrologists to formulate a study on existing wells within the one mile radius of the contamination just to keep an eye on the plume mobility."

Response to Oral Comment 7-1: The Department appreciates your comment. The Department's investigation of the Site is ongoing. A Licensed Professional Geologist employed by the Department is involved in the investigation of the Site. Additionally, the Department has retained the services of Professional Geologists through its General Technical Assistance Contractor to assist in the Site investigation.

Oral Comment 7-2:

"I don' t -I don't think this is an accurate, you know, estimation of the areas affected since not every single person got their well tested. I don't know if there 's any way to say, hey, we got everybody has to get it tested to really make the...."

Response to Oral Comment 7-2: The Department does not regulate privately owned residential potable wells and cannot require the owners of such wells to sample for PFOS and PFOA. Site investigation activities are ongoing and include the collection of additional groundwater data to aid in determining the nature and extent of contamination.

Oral Comment 7-3:

"......I'd also love you to - to also have the hydrologists formulate a specific study on the effects of discharging this pad of water up here at the quarry because that 's in the area .That's in a one mile radius. There is such a thing as hydrostatic pressure that has a devastating effect on wells. I don't think any of us wants to have to deal with this in a way that it's- it's happened and then now we can't do anything about it or its devastating effects after. So if you could have a professional hydrologic study done on plume mobility and the potential for the enlargement of the contamination within our wells we'd appreciate it very much."

Response to Oral Comment 7-3: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-1 regarding the purpose of the Interim Response. The Department's investigation of the Site is ongoing, and its findings are being shared with the Department's Mining Program which is responsible for the permitting of the quarry.

Oral Commenter #8: Dave Watt. Transcribed on page 46 of the hearing transcript:

Oral Comment 8-1:

"I'm on Perkasie Regional Water Authority water, so I was not affected by this. I also sit on the Board of Perkasie Regional Water Authority. I just want to put on record that I heard you have a budget, as we all do, on what you can do to fix this . I request that DEP meet with our Board. We're going to have a daytime meeting or a nighttime meeting so we can come up with a possible solution. I believe within a year's time or sooner we could service all 12 of those in red for less than your \$2 million budget, which would leave money left over for the two that you have in arch to put the filters in. And I still think it would be under that \$2 million:"

Response to Oral Comment 8-1: The Department appreciates your comment. The Department met with the Perkasie Regional Water Authority, East Rockhill Township, and West Rockhill on August 6, 2018 and with Perkasie Regional Water Authority on August 22, 2018 to discuss the scope, costs, and timeline of the extension of a water line to the Site.

Oral Comment 8-3:

"We 've already asked, I believe it was someone in DEP, if they wanted to use those wells for monitoring purposes or if they wanted us to close them. We have not heard back yet, so we offer that, too."

Response to Oral Comment 8-2: The Department appreciates the offer to sample the wells and will contact the Perkasie Regional Water Authority if it determines a need to do so.

<u>Oral Commenter #9:</u> Sue Furlong. Transcribed on page 46-47 of the hearing transcript.

Oral Comment 9-1:

"I'm just curious with the \$2 million if there will be some sort of a running total where people can find out, okay, this, this and this person paid X amount to get their system in, so that would reasonable amount. If out to a vendor, you know, just even just that kind of knowledge would be helpful so that they they can control their costs or maybe even four or five people could go together and a vendor would be able to get them a discount, that kind of thing is there a public accounting for that \$2 million? Let's say that they spend \$1.5 million. Is that remaining amount put into escrow so that if additional problems pop up later the 1.5 is still available? ou know, nobody shuts the book on it .How does that work? That would be my question. Thank you."

Response to Oral Comment 9-1: The Department appreciates your comment. Under the HSCA definition of "interim response," an Interim Response may not exceed \$2,000,000 in cost except in certain limited circumstances. The two million dollars discussed at the public meeting on July 11, 2018 was a reference to this statutory limitation; it is not the available budget for the Site. The

Hazardous Sites Cleanup Fund provides the funding for the Interim Response. Cost is one of the factors that the Department uses to evaluate the proposed interim response actions because it is the Department's responsibility to select a remedy that is cost effective. The Interim Response associated with the installation of filtration treatment systems is estimated to cost \$102,860. There is no escrow account established for the homeowners. Records regarding the costs at the Site are available at the Rachel Carlson State Office Building for review.

As stated in the Department's response to Comment 1-3, at the end of the twelve-month period in which the Department is taking responsibility for the sampling and maintenance of the carbon filtration systems, the Department will evaluate whether any of the circumstances exist that would allow an interim response to exceed twelve months in duration under the HSCA definition of "interim response" and, if so, whether the twelve-month period should be extended accordingly.

When sampling and maintenance of the carbon filtration systems become the responsibility of the homeowners, the Department recommends that homeowners contact multiple vendors and/or laboratories to obtain quotes for this work.

Subject: Comment about PFC water contamination Ridge Run Site Sellersville PA

Hi Lena,

For 20+ years citizens in our neighborhood have been drinking this poisoned water (re: Ridge Run PFC site).

Within the past 8 years, we've seen neighbors die from colon and breast cancers; a young child taken by leukemia; classmates of my child suffering from Tourette's; and our own child stricken with autoimmune disorders—inflammatory bowel disease and PANDAS.

The EPA has connected all these diseases to PFOA/PFOS exposure.

However, your response does not include PFOA/PFOS blood testing or monitoring for us.

For 20 years, we drank this fouled water. It's irresponsible to tell us everything is okay now that you've closed the poisoned wells and switched our water supply to Perkasie Water Authority. Like the people in Warrington PA who drank the PFC-tainted water from the naval base, we need blood testing and annual health monitoring. We need to be ensured that the PFOS/POS isn't hiding in our hot water tank sediment, continuing to poison us.

I REQUEST:

- 1. Testing of our water tank sediment as previously requested in an unanswered email to EPA. If found to be positive for PFOS/PFOA, water tanks should be replaced.
- 2. PFOA/PFOS blood testing for those who drank water supplied by tainted wells.
- 3. Ongoing health monitoring for those victims found with elevted blood levels of PFOS/PFOS.

The EPA chose not to test any potable water within any of the homes switched over to Perkasie Water. Why didn't you?

Can you guarantee us there are no PFOA and PFOS in our hot water tanks, in our water pump boosters, or our water softeners?

Thank you.

Kelly and Jerry Jameson
High Point Circle
Sellersville. PA 18960

Response to Written Comment 1-1: The Department appreciates your comment. This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-1, Response to Oral Comment 2-1, Response to Oral Comment 2-2, and Response to Oral Comment 2-3 regarding the purpose of the Interim Response, testing of drinking water of residential consumers on public supply wells, blood testing, and health monitoring, respectively.

Written Commenter #2 Jodi Cutaiar

Written Comment 2-1:

Sent: Friday, July 13, 2018

Subject: West rockhill residence

Hi!

I was there for the meeting the other night. Here is my voice. I have many concerns along with my neighbors.

- 1. My house value came down \$20,000 since the news of this water. Having a carbon filter as you suggest is not going to change that value since it needs to be enclosed in any documents for the house and state. This is my house and have the decision to what I want in my, house and it's not carbon filters. That is one more thing I don't want to do or think about. Our home is part of our investment. I want to expand it and to see value.
- 2. The investigation for your water source contaminate... I thought that was interesting you all said that. Your company samples water. Not soil, not inspect buildings nor investingate material things. The word investigate is a strong word to use.

- 4. Please get other authorities involved such as East Rockhill. Please talk to the builder. Please have a open mind to public water and finding that solution can be used in everyone's avenue.
- 5. The difference between a 3 year money comparison of filter or public. The difference was \$200.00. There are at least 2 things that I don't have to do with public. I would pay the 200 extra. Life is busy enough. I have 2 young kids, run two business and my, husband travels all the time. I have enough to think about.

I wish you all (on your panel) could put yourselves in this mind frame of our situation. Wouldn't you want a solution that's helps your family, your house value and be easier.

Thank you for reading this. Please find a way to public water..

Thank you

Jodi Cutaiar

Subject: Water

Hi again,

I emailed you yesterday about my thoughts on the carbon filters YOU want to put in. HERE IS MORE.

Did you check the soil for contaminates in your investigation?? I am not thinking you did. That will tell you A lot. How deep is the contaminates and if it would "plumm"

Digging 4 feet into the ground for public water would cause the chemicals to shift? You told a neighbor of mine that if the filters were installed you would stand by for 3 years and stand by and test them. Now you are saying one !!?? I saw and read the email.

PLEASE... NO FILTERS. Please talk to the builder, the east rockhill township leaders and please take our voices and put in public. YOUR PANAL IS NOT LIVING IN OUR HOMES!!

Response to Written Comment 2-2: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 3-2 regarding soil sampling at the Site. Please see the Department's

Response to Oral Comment 1-2 regarding why Alternative 3 was selected over Alternative 4 and how the Department will ensure the protectiveness of the Selected Response. Please see the Department's response to Oral Comment 1-3 regarding the time period of the Interim Response. Please see the Department's Response to Oral Comment 8-1 regarding meetings with municipal officials.

Written Comment 2-3:

Subject: Re: West rockhill residence

Hi Colin.

Thank you for getting back to me! I sent another email Saturday to Lenna about more concerns I had. Could you also take note of that one as well.

Just FYI. This situation is noted in the Doylestown paper as well. Please find a way to make my neighbors and my house have public water so WE don't have to deal with this anymore!!! Thanks for taking the time and reading this and making note.

Jodi Cutaiar

Response to Written Comment 2-3: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-2 regarding why Alternative 3 was selected over Alternative 4 and how the Department will ensure the protectiveness of the Selected Response.

Written Comment 2-4:

Sent: Tuesday, July 17, 2018

Subject: Re: West rockhill residence

Hi!

I have another concern...

My real estate tax just came in. Not only my house value went down Now my land value went down too. Uhm, that never happens.

Putting in a filter is not going to change any of that. As I stated before. You buy a house for part of an investment. Well.. Right now and, your thoughts of action.. Is not good news for us 12 houses.

Response to Written Comment 2-4: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 3-1 regarding the purpose of the Interim Response and the valuation of real estate.

Written Comment 2-5:

Sent: Wednesday, July 18, 2018

Subject: Re: West rockhill residence

Thanks.. I have more concerns.

I just read an article about PFAS.. IT EAS WRITEN JULY 16TH.. About the harmful facts. The are stating that it's from firefighting foam.

My, question: how many forms are you testing for PFAS? The normal is 6, but there are 14. If that is true. Our filters would get "clogged" faster than you suggest. Costing us a lot more money after your year of checking.

Thanks for checking into this

Response to Written Comment 2-5: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Oral Comment 1-3 regarding sampling and maintenance of the systems. Drinking water samples at the Site are being analyzed for PFOS and PFOA via USEPA Method 537 Revision 1.1. PFOS and PFOA are the only two PFAS compounds for which a HAL has been established.

Written Comment 2-6:

Hi.

I have been looking into the longevity of PFOAS and the chemicals chains.

I then looked at the fire back in 86 at Bergeys. Crazy that over 150, 000 tires were PUT on fire. The description of what happen seems horrifying.

My question to you guys.. If you have it...

The EPA came out 2 days after the fire and tested the water because of the foam that was used. The effects were know to contaminate water.., why was there no follow ups like in a year, 2 years. 5 years

It takes more than 2 days for anything like foam to get to the water table since there is not a actual water source. Ie, creek or pond. The EPA and the DEP kinda lost us or someone had an answers and that seemed good enough!!!

The proper people who do these test should have know to come back times later and tested the water. The other articles I read where the foam was used. Water was tested later and so was soil and blood samples were done.

Nothing like that has happened here before or even now to that extent. Why not

Response to Written Comment 2-6: The Department has no records regarding sampling performed by the United States Environmental Protection Agency in 1986. In August 2016, the North Penn Water Authority conducted sampling for six PFAS in two public water supply wells in East Rockhill Township in accordance with the federal Unregulated Contaminant Monitoring Rule 3. Analysis of these samples detected combined concentrations of PFOS and PFOA of 117 ppt and 70 ppt in these wells, both at or above the HAL. Approximately 167 properties have been sampled by DEP in the subsequent investigation of privately owned wells in the surrounding area.

Written Comment 2-7:

Sent: Tuesday, July 31, 2018

Subject: Re: West rockhill residence

Hi..

I know you are not going to answer my questions right now, but I want this down in my stock pile of questions I have. And I hope the are answered at the end of this public comment time.

So, in doing more research. What relation do you have with the EPA in dealing with water issues such as ours?

The reason I ask, the contamination in our area was in 1986. 2 days later the EPA came out to test the local water. In 1997 it is stated in documents that foam was toxic and started to test areas in about 2001.

Most of the areas tested were military based. My second question is this.. And others If documentation in 97 was stated and testing to certain areas in 2001. Why were we not on the list?? Why didn't the EPA come out like they did the first time in 2001. Why are you in charge of this area and the EPA is in charge of Willow Grove area??

Thanks for taking a read and I, hope to hear these answered in up coming meetings

Response to Written Comment 2-7: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Written Comment 2-6 regarding USEPA involvement at the Site in 1986. The Department's investigation of the Ridge Run PFAS HSCA Site is being conducted under the Hazardous Sites Cleanup Act of 1988 which grants the Department the authority to investigate the release, or threat of release of hazardous substances or contaminants in the Commonwealth of Pennsylvania. The former Naval Air Station Joint Reserve Base Willow Grove is a federal Superfund Site, being investigated under the federal Comprehensive Environmental Response, Compensation and Liability Act of 1980 by the United States Navy with USEPA and Department oversight.

Subject: West rock hill

Hi again.

This water situation we have is more complex far more than I ever first thought.

So... I have another question and I would love an answer now, but I know later and looking forward to this later too.

I discovered that are 3 chains in the PFAS. You only were testing for 2. Why not test it all. PFC is the third chain and it too is in foam of fighting fire and other solvents.

I saw the other 2 are able to stick to fats and the other chain sticks to more protein and. All of these chemicals are horrible on so many levels.

Again, why did you only test for 2.. not all 3?

That could be in our water source, clog up filters or maybe not be held back by a filter!? Another reason why to give us public water.

I look forward to the auto response.

Jodi Cutaiar

Subject: West rock hill

Hi to the both of you.

I never imagine in my life time that I would be doing so much research and discovery about water, especially my water.

From the start of learning about the fire and what was used, man power and what happened in the aftermath made me think more about burning tires.

Yes, burning tires! The outcome of what happens when rubber is set on fire. In our case at least 50, 000 tires! There was a study about buring tires in 1989. That was 3 years later from our disaster. More studies and discoveries in 1992.

Results: PAHS and BaP were found. Yeah, the large cancer combo was found.

Burning tires are 3 to 4 times more greater than other burning components.

My question, and I know you can't answer but I am expecting an answer after the final decision, the EPA knew about this because it was their study. Why not do more and investigate soil, water.. scum from tire fire is huge and not even in your water test.. but.. you are just testing Only 2!! No more because your not a 100% certain on the explanation of why we have our problem. Right!? This whole water situation at this present time could of been avoided if we were not a small community with someone trying to not make a big deal of 1000's of tires burning and then foam being used. Let's do the right thing this time and not make history repeat itself.

I hope you both have a great rest of your week and I am looking forward to the decision date. Jodi Cutaiar

Response to Written Comment 2-9: This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Please see the Department's Response to Written Comment 2-6 regarding USEPA involvement at the Site in 1986 and sampling for PFAS at the Site. Subject: Water

Hello Lena, I was wondering where are standing. I know there was a meeting. Not much information there that we didn't all ready know. I am very concerned about having filtration systems put into place here now. One issue I foresee is our homes will still be contaminated. No person in their right mind would purchase a home with contaminated water. Filter system or not. A filtration system will only last for so long and how are we to know if contaminants would not pass through this prior to the regular maintenance? Interesting fact to know that one part of a person's body that does not absorbs water is through the skin. However it's also a fact that certain chemicals can be absorbed through the skin. Is there testing done on these chemicals to see if this is a fact? I know we are not to ingest the water, but how do we truly know damage is not being caused in other ways or has allready been done? I see no other testing being done to prove these points. I also see no other investigating going on to find out who is at fault. Who is at fault? Not the homeowners dealing with this. How do we know that years of drinking this water has not onset certain health conditions that may have otherwise been prolonged? No further testing again. You have only been testing for a little over a year and have seen the fluctuation on the properties. How do we now we were not at very dangerous levels for years after the fire and up until 2 years ago? We dont! I have lived in my home for 18 years now. Your not living with this problem, we are. My home has depreciated due to this, Not yours. I feel we should now be provided public water to resolve this issue. What is being done? What is the next step? More meetings? more testing? No resolutions!

Colin,

Thank you for responding to me after almost a week, but you did not address my question AT ALL, instead you talked around it.

A year ago I was told that soil testing would be done and at the meeting it was mentioned. I would like to know when this will be done?

I appreciate you will share your findings with us but we (the homeowners) have a lot we are losing here. I can tell you personally that we have done a lot to our home and we have just lost all the value that we worked for. I would like to invite anyone of you to my property and I will show you exactly what I am talking about. This is not a trailer park, we cannot just hook up our homes and move. I have good neighbors, we look out for each other, we do not deserve to be going thru this.

Only your office has the authority to do the testing and we need all the help you can give us. Thank you for your time,

Angela Goodwin

Written Comment 4-3:

Sent: Thu, Aug 30, 2018

Subject: Fwd: Comments for Ridge Run contamination

1) Our families health, our property values and our community have been compromised and the only thing that would help is public water. Would you buy a home with a contaminated well?

- 2) The filtration system does not have an alarm system to let us know when the filter needs to be replaced. We could have our water tested and then 6 months later the filter could be bad. We would then be back to dealing with contaminated water and not even know it. We would always be worried about using too much water and the filter needing to be replaced. People have pools and hot tubs that need to be filled occasionally, we would be afraid to do that because of the filters. We will never be able to lead a normal life with the filtration systems.
- 3) You mentioned that if you shut down wells the contamination could go elsewhere. Well the highest levels are right around Bergey's property, so "A" why are we supposed to be punished for something that we had nothing to do with and not control over, "B" what about new wells going in, you will be drilling new wells to keep checking will the water, new homes go up all the time and what if current residents need new wells, that also can change things.
- 4) You mentioned at the meeting that after you finish your investigation you will be going after the party you feel is responsible for this. You mentioned that we would then have to go after this party to recoup our lose, but we have reached out to 7 attorneys and we have not been able to get anyone to represent us. We are too small of an area and they all seem to be representing residents around the Navel Air Force Base. So without public water the residents with contaminated wells really have no value in their properties and no way to recoup any losses, plus we have to hope our health is not affected.
- 5) Representatives from East Rockhill Township and Perkasie Water Authority were present at this meeting and they mentioned they could bring us public water for under DEP budget amount, but DEP mentioned that private wells are really not their concern, that private wells are the responsibility of the owners. We the owners did not cause this contamination, it would be nice to have our government looking out for us.
- 6) We all know that the responsible party is Bergey's. I have copies of newspaper articles from back in 1985 and 1986, they had tires piled up for 5,6,7 years. Per the township comments that was not allowed. The year before the fire they were supposed to be cutting them in half and recycling. You can tell from the pictures from the fire they were not. They had over 3 million tires piled up. If there was not so many tires piled up they may not have had to use the spray foam. According to the one article "it really did not help".
- 7) From what I was told this spray foam was all over my property and the neighbors (we purchased our property in 2000 and the tires were/are in trailers). The previous owner and neighbors had asked the township and fire department about coming back to clean this up but no one responded. As of this point the soils on my property may also be contaminated and I have asked about doing soil testing but I get no response.
- 8) There is a retention basin behind my property. This basin use to drain on the vacant lot next to my property. Back in 1986 after the fire the EPA monitored the clean-up of Bergeys and the water in the basin. After it was okay they allowed this water to be released. EPA then test the stream that they THOUGHT this water was draining too but it never made it that far. As of this point the soil all around my property could very well be contaminated and we still deal with water running from Bergey's property onto mine.

Public water is in our best interest and should not be what fits in a budget, especially when you are talking about someone's health.

I have attached 2 pictures of plants that I did an experiment on. They were both planted at the same time. I used the same soil in both pots. I gave them the same amount of water at the same time. The only difference was I used bottled water for one and well water for the other. I did not use fertilizer on either one.

Look at the difference between the 2 plants in only a month with little sun. Now think what they would be like after a couple months. So what is happening to our health from our water?

It would be nice if we the residents would have a vote on what you would like to do with OUR properties.

Thank you,
Angela Goodwin

Subject: Water Issue

Ms. Harper,

We at Sold Bethlehem Pike would like to voice our opinion on our water issue, we would like to go on record as requesting we have public water piped in to our residence. There are several reasons we request this, First we agree with Mr. watt that there is a better way to pipe in the 12 effected homes for far less then quoted and we do not agree it will shift any contaminants to other water systems. Second, this property is commercial and we have a business here that requires the use of large amounts of water and safety of our customer is #1 priority. Third I am a disabled individual and I would not be able to maintain any kind of water filter system, not to mention I am on a fixed income and would not be able to afford another maintenance bill. Finally we do not except a carbon filter system as a permanent fix to this problem. Who would be responsible for damages to health etc.. if we find out later that filters did not 100% eliminate the pollution in the water. Public water is the only way to assure 100% that our drinking and bathing water is safe and we feel it should be up to the effected homes/People to decide on a solution and with no time frame to do so, no one else. We will get into personal damages and financial damages at a later date. Sign us up for Public water please.

Thank You

Sheri

Written Comment 8-1:

Sent: Tuesday, August 21, 2018

Subject: Carbon filters vs Public water

I live at Old Bethlehem Pike (almost, but not quite across the street from the end of Tabor Road), and my neighbors stopped by yesterday to discuss our wells and the Bergey's Tire Fire potential contamination. They sought to persuade me to support the installation of public water service. Sadly for them, I do not.

When I found out that there might be a problem, I did just a little research and discovered that the way to mitigate the problem was to use a carbon filter. So I bought one. The public utility will treat water the same way - with a carbon filter.

My neighbors are concerned with the cost of these filters. I agree - it's an expense I did not have a year ago. However, in my experience, the proposed \$750 per year it will cost is still less than another utility bill for the year. The neighbors also are suggesting that Bergey's help pay for the solution. Why would they? Bergey's didn't start the fire, it was determined to be arson. Find the arsonist and bill that person. Additionally, Bergey's didn't specifically ask the Navy to come up from the Willow Grove Naval Air Station and use chemical-laden foam to try to suppress the fire. Send the bill to the Navy. (It appears that the military found out multiple years after this incident that the foam chemicals had health risks, so maybe don't send them the bill. They were acting in good faith it seems.)

Finally, President Reagan was right when he said, "The nine most terrifying words in the English language are, 'I'm from the government and I'm here to help.'" Municipal water being supplied to these homes is no guarantee of safe water being supplied, as we learned from Flint, Michigan. I will take responsibility for providing safe water for my family, thank you very much.

Chris LaBelle, MS Lecturer Department of Chemistry & Biochemistry Holroyd Science Center 343

Response to Written Comment 8-1: The Department appreciates your comment. The Department has selected Alternative 3, the installation of Whole-house Filtration Systems with Restrictions on the Use of Groundwater as the Interim Response at the Site.

Written Commenter #9: Andi Stephenson

Written Comment 9-1:

- 1. Charcoal Filters not a permanent/fail-proof solution. Too many variables.
- 1. Don't care for the fact that mention of water issues would be added to property deeds...
- 2. Long term public water solution and maps have indeed been discussed and shared with DEP as per East Rockhill Township official.
- Lines would run up Park/Old Beth Pike up to and including the Lapp properties, an "L" at Three Mile Run Road would run up to Tunnel Road, an "L" at Hill Road would run up to Stone Edge Road, where the line would connect to the Ridge Run Development current system.
- 2. Two million dollars of DEP funds have been promised and earmarked for the public water project. East Rockhill and West Rockhill are teaming up to come up with the remaining 1.3 million for the overall project.
- 3. Other than future quarterly water fees, there would not be an expense to the property owners that would be mandated to hook up to the public water.
- 3. Eye-witness account regarding the concealment of excess tires and foam product at time of the Bergey fire in 1986 are prevalent. Many burnt tires were removed from the property after the fire, some were not and these and the excess foam were buried.
- 1. Has this witness account been taken seriously?
- 2. Has the DEP conducted tests to the burn site that is now covered with macadam?
- 3. Will there be test of the area in the future?

I look forward to future meetings where additional information and discussions can take place with other affected neighbors.

Regards,

Andi Stephenson

Subject: Ridge Run PFAs - Public Comment

Hello Ms. Harper,

I am writing my public comment in response to the PFAs in the Ridge Run Development in East Rockhill Township, PA.

It is completely unacceptable that:

- 1) The source of the PFAs has not been discovered, leaving the DEP to pay for remediation, and leaving citizens to wonder if this may occur again, or occur in other places. The responsible party needs to be determined, and held responsible for the remediation costs.
- 2) The residents deserve to have COMPLETE remediation of this issue in the form of permanent connection to public water. It is unfair to install systems in their homes that they will be responsible for maintaining into the indefinite future, and will have to pass along to any new home buyer. I can see how that could possibly be reducing their property's value.

I am also concerned about an already compromised water system that is about to be taxed further by the Rockhill Quarry's re-opening, and the unethical behavior of RE Peirson (the company currently operating illegally at that site), that has applied for further, larger scale operations there (namely, a 1000 ton per hour crusher). I do not trust them to operate anything so large and dangerous in our community. I believe their history should prevent them from being given any further ability to damage our town. At the very least, extensive hydrological surveys and meaningful, enforceable restrictions need to be set into place. They will be using massive amounts of water, draining the quarry pit, and they already have issues with adequate surface and storm water management. Not to mention the fact that their traffic study didn't even touch on the more than doubled amount of truck trips that the proposed increase would generate. Will they be washing these trucks on site? What sort of chemicals may be washed into the soil and ground water from that?

Thank you,

Emily Geib East Rockhill Township, PA

Department of Environmental Protection Southeast Regional Office 2 E. Main St. Norristown, PA 19401 Attn: Ragesh Patel

RE: Ridge Run PFC Contamination

Dear Supervisors and Mr. Patel:

A joint meeting, with representatives from DEP, Perkasie Regional Authority (PRA), East Rockhill Township and West Rockhill Township, was held at the Perkasie Regional Authority offices on August 6th to discuss the potential of extending public water mains to some of the affected homes of the Ridge Run PFC contamination. The major items of concern are the current contamination, the ability to control any potential plume shift and the swiftness in which the solutions can be carried out.

Perkasie Regional Authority has directed its Engineer to look into the feasibility and cost of extending water mains to the majority of the affected area. In the event that water mains are extended as part of the contamination solution, our understanding is that DEP would require the following:

- I) All private wells would need to be abandoned and filled.
- Both East and West Rockhill Townships would be required to pass Mandatory Connection Ordinances for all properties within 100 feet of the water main, per DEP requirements.

1 | 1 3 3

3) The cost of connection to each homeowner with a private well would be \$0.00, provided that all DEP requirements are met.

A follow-up letter with cost estimates and maps will be provided once the PRA Engineer has conducted the due diligence. If anyone has any questions, comments or concerns please feel free to reach out to Nick at 215-257-3654.

Regards,

Nicholas Fretz

Written Comment 14-2:

Good Afternoon All,

I wanted to get everyone some final estimates and options along with a brief explanation of each, since today is the last day for comments.

Option #1:

This option is an all-encompassing option that includes over 11,700 linear feet of water main. In order for PRA to provide service to this entire area, a booster pump station would need to be installed at the Authority water tank. Although that cost of roughly \$1.3m is included in this estimate, that Authority Board would contribute this cost towards the project to install the pumps and generator.

Option #2:

This option is a slightly slimmed-down project with over 7,100 linear feet of water main. Since there are financial concerns with providing service, this option is a viable option because it is under the \$2m threshold that DEP is legally allowed to spend on the contamination clean-up and this will serve all of the customers with private wells above the 70 PPT HAL. In addition, since the water mains in this option do not extend as far north on Old Bethlehem Pike compared to Option #1, a booster pump is not needed to provide service.

If anyone has any questions or would like a more detailed explanation, please don't hesitate to call or contact me.

Thanks and I hope everyone has a great holiday weekend.

Nick

Subject: Ridge Run Well Contamination Written Response

I am writing to express my strong concerns about PA DEP's proposed response to allow clean water for the affected residents of the Ridge Run contaminated PFAS site. I fully feel the whole-house carbon filtration system is a short term solution only and that a long term permanent solution needs to be considered. Therefore, I want to be on record saying that connection to the available public water system that is already in place approximately ¼ mile from our homes be made for a permanent and viable solution.

I am concerned that the whole-house carbon filtration system is a way for the PA DEP to fix the problem of PFAS contamination for the current affected 12 wells for the least amount of time and money and fits within the constraints of their budget and not what is best for the residents. This is evidenced by offering only a I year maintenance agreement and pay for the first carbon change out, if needed within the first year. But, according to DEP, One sampling event and one filter maintenance event are estimated to be needed once every 3-5 years. So the DEP is only paying for a sampling event within that first year! Remember, after one year, maintenance is then the responsibility of the homeowner. I believe this is woefully short of responsibility by the DEP and the other parties accountable. Additionally, the residents would be required to sign a covenant for maintenance of carbon filtration system and make aware to other parties that the wells are contaminated.

Please accept this as my on the record written response to the Ridge Run PFAS contamination clean-up proposal. My recommendation and hope is providing the connection to the already available public water supply is the plan selected by the PA DEP!

Thank you,

Gerald M. Moyer
Tabor Road
Sellersville ,Pa 18960

Written Commenter #16: Peter McClennen. Attachments are included in Appendix D.

Written Comment 16-1:

August 31, 2018

On July 10, 2010 Anderson Engineering gave me this plan when a developer took me to his office for a meeting.

For a couple of years Anderson Engineering had been trying to establish water and sewage lines in West Rockhill Twp. on Bethlehem pike between Rt. 563 and the 3 Mile Run Creek, as indicated by the green lines on this map. It was suggested that the sewage could be diverted to a sewage pump located on my property. The location was to be at the site of a well I had drilled in the late 1980's. Of course I told them no.

When I had this well drilled a county inspector claimed it to be one of the best wells in Eastern PA. Ever since the well was established a few people have discouraged any use of it being used in a public capacity. This well produces over 400 gal. per minute of beautiful water, with a PFOA of less than 3, that runs out of a $1.1/2^n$ pipe into the 3 Mile Run Creek.

Actually this system could supply water and sewage to a majority of the area in West Rockhill Twp. north of the Ridge Road. If nothing else the well could supply good water to the folks on Old Bethlehem Pike and Tabor Road.

Can you imagine bathing in or drinking the water they have now, even with a filter? This could bring them much needed sewage as well as water and it could happen now at a much more reasonable cost to the homeowners. I hate to think of the mental suffering as well as the physical problems these people have been going through.

The other plan submitted shows the large wet land between Bethlehem Pike and Old Bethlehem Pike caused by the bridge but mainly by the old Liberty Bell trolley bridge abutments. This would favor the sewer line being on the North side of the 3 Mile Run Creek.

PCMC

Response to Written Comment 16-1: The Department appreciates your comment. This comment is similar to previous comments, so the Department will refer you to its responses to those comments. Subject: Fwd: Comments for Ridge Run contamination

- 1) Our families health, our property values and our community have been compromised and the only thing that would help is public water. Would you buy a home with a contaminated well?
- The filtration system does not have an alarm system to let us know when the filter needs to be replaced. We could have our water tested and then 6 months later the filter could be bad. We would then be back to dealing with contaminated water and not even know it. We would always be worried about using too much water and the filter needing to be replaced. People have pools and hot tubs that need to be filled occasionally, we would be afraid to do that because of the filters. We will never be able to lead a normal life with the filtration systems.
- 3) You mentioned that if you shut down wells the contamination could go elsewhere. Well the highest levels are right around Bergey's property, so "A" why are we supposed to be punished for something that we had nothing to do with and not control over, "B" what about new wells going in, you will be drilling new wells to keep checking will the water, new homes go up all the time and what if current residents need new wells, that also can change things.
- You mentioned at the meeting that after you finish your investigation you will be going after the party you feel is responsible for this. You mentioned that we would then have to go after this party to recoup our lose, but we have reached

out to 7 attorneys and we have not been able to get anyone to represent us. We are too small of an area and they all seem to be representing residents around the Navel Air Force Base. So without public water the residents with contaminated wells really have no value in their properties and no way to recoup any losses, plus we have to hope our health is not affected.

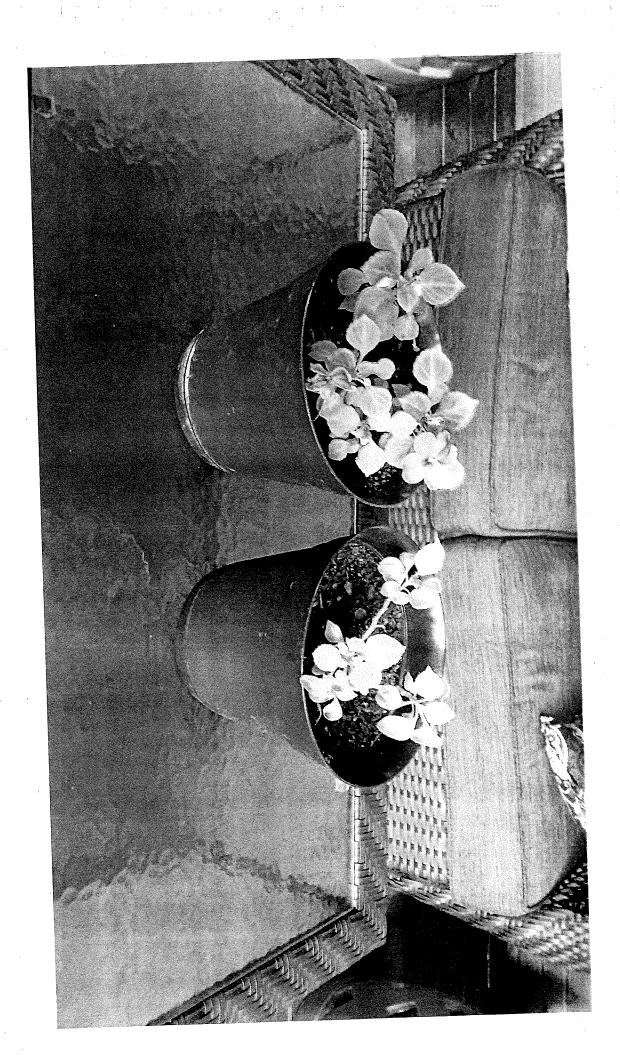

- 5) Representatives from East Rockhill Township and Perkasie Water Authority were present at this meeting and they mentioned they could bring us public water for under DEP budget amount, but DEP mentioned that private wells are really not their concern, that private wells are the responsibility of the owners. We the owners did not cause this contamination, it would be nice to have our government looking out for us.
- 6) We all know that the responsible party is Bergey's. I have copies of newspaper articles from back in 1985 and 1986, they had tires piled up for 5,6,7 years. Per the township comments that was not allowed. The year before the fire they were supposed to be cutting them in half and recycling. You can tell from the pictures from the fire they were not. They had over 3 million tires piled up. If there was not so many tires piled up they may not have had to use the spray foam. According to the one article "it really did not help".
- 7) From what I was told this spray foam was all over my property and the neighbors (we purchased our property in 2000 and the tires were/are in trailers). The previous owner and neighbors had asked the township and fire department about coming back to clean this up but no one responded. As of this point the soils on my property may also be contaminated and I have asked about doing soil testing but I get no response.
- There is a retention basin behind my property. This basin use to drain on the vacant lot next to my property. Back in 1986 after the fire the EPA monitored the clean-up of Bergeys and the water in the basin. After it was okay they allowed this water to be released. EPA then test the stream that they THOUGHT this water was draining too but it never made it that far. As of this point the soil all around my property could very well be contaminated and we still deal with water running from Bergey's property onto mine.

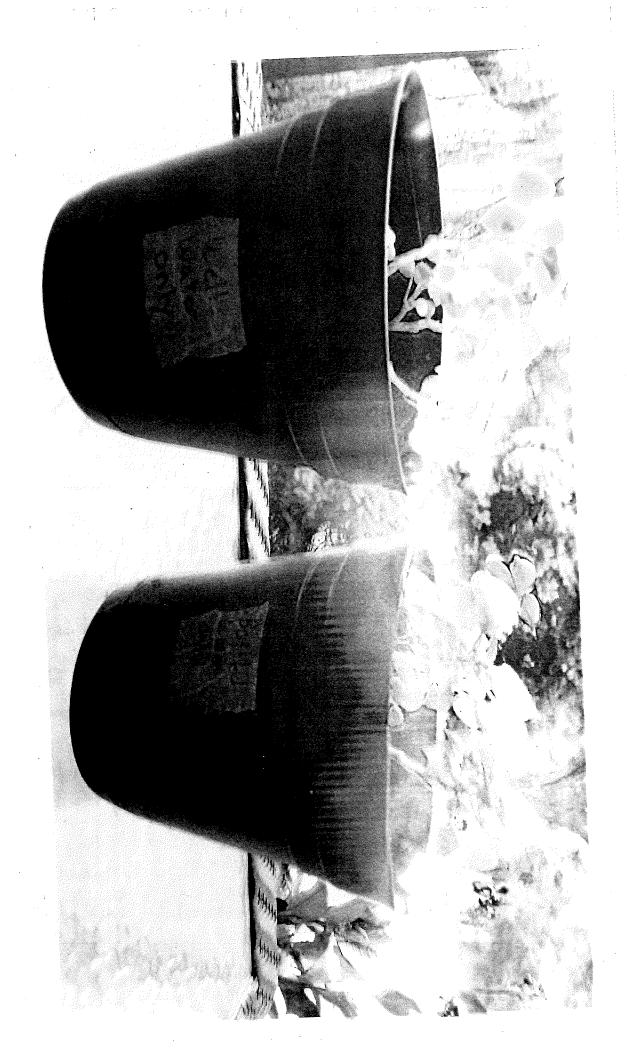

Public water is in our best interest and should not be what fits in a budget, especially when you are talking about someone's health.

I have attached 2 pictures of plants that I did an experiment on. They were both planted at the same time. I used the same soil in both pots. I gave them the same amount of water at the same time. The only difference was I used bottled water for one and well water for the other. I did not use fertilizer on either one. Look at the difference between the 2 plants in only a month with little sun. Now think what they would be like after a couple months. So what is happening to our health from our water?

It would be nice if we the residents would have a vote on what you would like to do with OUR properties.

Thank you, Angela Goodwin 1730 Tabor Road Sellersville, PA

PADEP, Hazardous Sites Clean-Up UNDER THE ACT OF October 18, 1988

NOTICE OF PROPOSED INTERIM RESPONSE

Ridge Run PFAS HSCA Site, East & West Rockhill Townships, Bucks County, PA

Please find attached a copy of testimony submit by Tracy Carluccio, Deputy Director, Delaware Riverkeeper Network at the PADEP July 11 hearing. This comment may be slightly different than that verbally presented due to shortening the length due to time constraints at the hearing.

Also please find copies of the technical reports commissioned by Delaware Riverkeeper Network regarding:

- PFOA: Recommended MCL; PQL; Treatment Options (3 PDFs)
- PFOS: Recommended MCL; PQL; Treatment Options (1 combined PDF)

Please consider these reports as supporting the testimony made to PADEP at the July 11 Hearing and in the written version of that testimony attached hereto.

Thank you for the opportunity to submit these written comments,

Tracy Carluccio

Lena Harper Environmental Protection Specialist Pennsylvania Department of Environmental Protection 2 East Main Street, Norristown, PA 19401

TESTIMONY of Tracy Carluccio
Deputy Director, Delaware Riverkeeper Network
to Pennsylvania Department of Environmental Protection (DEP) re.
Hazardous Sites Clean-Up UNDER THE ACT OF October 18, 1988
NOTICE OF PROPOSED INTERIM RESPONSE
Ridge Run PFAS HSCA Site, East & West Rockhill Townships, Bucks County
July 11 Public Hearing
West Rockhill Township, Bucks County

Delaware Riverkeeper Network (DRN) presents this testimony regarding the proposed clean-up of per- and poly-fluorinated alkyl substances (PFAS) above the US Environmental Protection Agency's (EPA) Health Advisory Limit (HAL) combined concentration for Perfluorooctane sulfonate (PFOS) and Perfluorooctanoic acid (PFOA) of 70 nanograms per liter (ng/L) or parts per trillion (ppt).

We have a few points to make today:

First, we do not agree that applying the EPA HAL of 70 ppt is reasonable or protective and using it can mask how much contamination actually exists. In June, the federal Agency for Toxic Substances and Disease Registry (ATSDR) released "minimum risk levels" that reduce the level at which no harm can be expected from exposure down to approximately 7 ppt for PFOS and 11 ppt for PFOA. PFAS is highly toxic and linked to devastating disease such as cancer. Even miniscule concentrations in drinking water can have adverse health effects. Additionally, other states are considering safe drinking water standards that are many times lower than the EPA HAL and more in line with ATSDR's findings.

DELAWARE RIVERKEEPER NETWORK 925 Canal Street, Suite 3701 Bristol, PA 19007 Office: (215) 369-1188 fax: (215) 369-1181 drn@delawareriverkeeper.org www.delawareriverkeeper.org New Jersey, for instance, is going to adopt mandatory maximum contaminant levels (MCLs) of 14 ppt for PFOA and 13 ppt for PFOS, dropping the trigger in that state for mandatory treatment by all water suppliers to a much lower and more protective level.

Finally, DRN filed a formal petition with Pennsylvania's Environmental Quality Board (EQB), asking that they set a MCL for PFOA of 1ppt or no greater than 6ppt. The EQB accepted our petition last year and is currently considering setting a MCL. We recently brought to the EQB's attention the final recommendation and findings of the NJDWQI for a MCL for PFOS and submitted DRN's report prepared by an independent toxicologist recommending a MCL of a maximum of 5 ppt or "non-detect" for PFOS.

Based on the most recent science, the trigger for remediation and water replacement for people should be either at non-detect or no greater than 5 ppt for PFOS and between 1 and 6 ppt for PFOA. You refer in your presentation here tonight to identifying 12 wells with PFCs in this area. However, the summary of groundwater sampling that you provided for review shows many more than 12 wells with detections of PFOA and PFOS above 5 or 6 ppt, singly or combined. Using these levels as triggers increases the number of wells that require treatment and substantially changes DEP's evaluation and the cost analysis – both the total cost and the distribution of the capital costs of treatment. This is especially true if PFAS is detected in more wells as sampling continues.

DRN supports DEP's proposed Alternative 4, the piping in of public contaminant-free water, to provide the protection needed. Extending the public water system could be coupled with Alternative 3 by immediately installing whole house filtration systems or continuing the use of bottled water until the piped system is operating. The installation of whole house filtration systems could be used in combination with Alternative 4 to cover outlier wells that are outside the area that would be reasonably served by the extension of the existing water system. Extending the water system and using the bottled water or whole house filters in the meantime will provide immediate long-term relief for an already impacted community.

However, Alternative 3's condition of turning the systems over to the homeowners after 1 year is unacceptable and unfair. The systems should be monitored and maintained by DEP or the responsible party in perpetuity.

DRN supports that action be taken by DEP as swiftly as possible to address the groundwater contamination in the Ridge Run area. The public and DEP are well aware of the highly toxic properties of PFAS and the threat these compounds represent to human health. Contaminated drinking water is the major source of ingestion of PFAS. Because there are numerous individual water wells and at least two – now closed - public water supply wells that are known to be contaminated at this site, because the source of the contamination has not been conclusively defined, because the groundwater aquifer is known to contain the compounds and because these compounds do not break down in the environment but persist indefinitely and can spread over time, because PFAS builds up in peoples' blood, increasing the risk of harmful health effects, and people here do not know how long they've been exposed and at what level, it is critical that action be taken on urgent footing to protect public health and the environment.

Regardless of the solution, it is vitally important that the environmental cleanup of the pollution commences in tandem with the drinking water solution and the source be found and the responsible party be made accountable. That would provide a truly permanent solution.

Thank you for the opportunity to comment on this important contamination issue and thank you for taking action to remedy this egregious pollution problem.

watersupply@dep.nj.gov New Jersey Department of Environmental Protection Trenton, New Jersey

Re: Comment on the Proposed DWQI Addendum to Appendix C: Recommendation on Perfluorinated Compound Treatment Options for Drinking Water

Please find enclosed a technical analysis prepared by Fardin Oliaei, MPA, PhD, and Don Kriens, Sc.D., P.E. of Cambridge Environmental Consulting commissioned by Delaware Riverkeeper Network and submitted on behalf of the organization and its membership on the Drinking Water Quality Institute's document Addendum to Appendix C: Recommendation on Perfluorinated Compound Treatment (PFC) Options for Drinking Water.

Also attached is a PDF containing the Curriculum Vitae for Dr. Oliaei and for Don Kriens, Sc.D., P.E.

Delaware Riverkeeper Network submits these comments advocating that the public be protected from PFC contamination and that New Jersey's drinking water be required to be treated to a safe level based on the best available scientific evidence and the most effective treatment technologies.

We support the recommendations and findings made by Dr. Oliaei and Don Kriens of Cambridge Environmental Consulting in this technical analysis regarding the Addendum to the Treatment Options Report by the DWQI. We support the utilization of the most effective methods of removing PFCs considering the highly toxic properties of the compound.

Dr. Oliaei and Don Kriens recommend that reverse osmosis (RO) is needed to completely remove all PFCs from drinking water to the proposed safe drinking water standard. Dr. Oliaei and Don Kriens also find that RO alone or used after granular activated carbon (GAC) represents the best available technology for this purpose. Delaware Riverkeeper Network supports these findings and advocates for the use of the best available technology with a goal of providing safe drinking water to the public.

Thank you for the opportunity to comment on the Treatment Options to remove PFCs, including PFOA, PFNA, and PFOS.

DELAWARE RIVERKEEPER NETWORK 925 Canal Street, Suite 3701 Bristol, PA 19007 Office: (215) 369-1188 fax: (215)369-1181 drn@delawareriverkeeper.org www.delawareriverkeeper.org

Technical Review of New Jersey Drinking Water Quality Institute's Recommendation on Perfluorinated Compound Treatment Options for Drinking Water

by

Cambridge Environmental Consulting

Executive Summary

We previously reviewed treatment technologies applicable to removal of PFCs at municipal drinking water supplies to remove PFOS, PFOA, and PFNA in our comments to NJDWQI proposed MCL for PFNA in 2015. This review updates our prior analysis of these technologies.

We found that reverse osmosis (RO) is needed to adequately remove all PFCs, including PFOA, PFNA, and PFOS, to proposed MCL standards. There are numerous installations across the U.S. where RO is economically applied to treat groundwater and, in some cases, surface water, as drinking water supplies. We believe that RO alone or RO after GAC (granular activated carbon) represents the best available treatment technology economically achievable to remove PFCs. Depending upon pilot studies and bench testing, nanofiltration (NF) may be a viable substitute for RO. RO preceded by conventional treatment (filtration) represents best technology at public water supplies using groundwater, and conventional treatment/coagulation-filtration followed by RO or a sequence of GAC followed by RO (or NF where applicable) represents best available technology for surface waters.

Introduction

In the U.S. the majority of municipal drinking water treatment systems use conventional water treatment technologies, which typically include flocculation and coagulation, filtration, and disinfection using chlorine or chlorine derivatives. Alternative disinfectants such as ozone are occasionally used which also provide for organics removal, and occasionally municipal systems use advanced technologies such as activated carbon. Conventional drinking water treatment technologies have little effect on PFC removal, including PFOS, PFOA, and PFNA. More advanced technologies are used to remove selective organic compounds and include, but are not limited to, advanced microfiltration technologies, such as ultrafiltration and nanofiltration, advanced oxidation processes, such as ozonation, peroxide, and UV peroxide, and reverse osmosis and activated carbon technologies. A combination of technologies may be applied where superior removals are needed, such as in water reclamation processes. A number of advanced water treatment systems using combinations of advanced technologies are in operation worldwide where recycled domestic wastewater is reclaimed and treated to very high quality (Queensland, Australia; Los Angeles; Singapore; Windhoek). These advanced systems, however, are used at locations where water scarcity is the primary constraint.

PFC compounds have relatively high molecular weight, at least for higher carbon number PFCs, that leaves them amenable to adsorptive removal technologies such as activated carbon. They are both hydrophobic and hydrophilic, although aqueous solubility varies greatly between PFCs. This duality can reduce carbon adsorption capacity for the carboxylic PFCs to some extent, although the hydrophilic portion of the molecule increases potential removal by membrane (reverse osmosis) and ion exchange technologies.

Cost is a consideration in addition to treatability of PFCs at municipal systems using various advanced technologies. Analysis of the economic benefits of reduction in health costs versus the cost of treatment (benefit-cost analysis) would be useful to assess overall social benefit of treatment for PFC at locations containing these contaminants in their water supplies. Cost-effective analysis would help to determine the most suitable removal technology. However, economic considerations are beyond the scope of this review.

Granular Activated Carbon

Granular activated carbon (GAC) has been shown to be very effective to remove most PFCs. GAC systems typically employ pre-filtration via sand or mixed-media filtration.

Some studies indicate that powdered activated carbon (PAC) versus granular activated carbon provides better PFC removal. One study found that powdered activated carbon generally showed better adsorption than granulated activated carbon, sulfonates were more strongly adsorbed than carboxylic acids, and PFC adsorption increased with increasing PFC chain length (Hansen et al., 2010). A study by Ochoa-Herrera found that PFOS is strongly adsorbed by GAC. PFOA and PFBS were also removed by GAC but to a lesser extent (Ochoa-Herrera and Sierra-Alvarez 2008). Results in this study indicate stronger adsorption to perfluorosulfonates as compared to perfluorocarboxylates at equivalent chain lengths. In a study by Arvaniti, PFOS, PFOA and PFNA were removed by nearly 100% using PAC, but at considerably lesser percent removals using GAC (Arvaniti 2013).

There are some municipal drinking water treatment systems in operation in the U.S. designed for removal of PFCs. In Oakdale, Minnesota a GAC system treats water for about 30,000 residents, meeting the current Minnesota drinking water standard for PFOA and PFOA of 300 ng/L (to be updated to the revised EPA standard of 70 ng/L). These limits are much higher than New Jersey's proposed limit of 14 ng/L. The quantitative analytical reporting limit for PFOA in Minnesota is 14 ng/L. Although Oakdale's GAC water is produced at levels below this limit it is unknown whether that GAC facility would meet a limit lower than 14 ng/L. The NJWQI report notes that PFNA is removed to less than detectable with a RL of 5 ng/L at the New Jersey American Water-Logan System, although no data is provided for PFOA.

The Minnesota Mining and Manufacturing (3M) Cottage Grove, Minnesota plant also uses a GAC system to remove PFCs from its wastewater discharge effluent to the Mississippi River. A 2006 study found a 79% reduction in PFOA and a 95% reduction in PFOS at the 3M GAC treatment system (Oliaei and Kriens 2006).

In summary, GAC has been shown to very effectively remove PFCs, in practice or via research studies, although the form of AC (GAC or PAC) could affect performance in some instances and individual PFCs are removed at different rates.

Reverse Osmosis

Reverse osmosis and nanofiltration are very effective to remove PFCs. Reverse osmosis resulted in greater than 99% rejection of PFOS, and nanofiltration resulted in 90-99% PFOS removal in a study by Tang et. al. (Tang 2007). The effectiveness of reverse osmosis treatment is shown by Quinones and Snyder (2009), where a utility using microfiltration and reverse osmosis in wastewater treatment for indirect potable reuse reduced total PFC influent of 80 ng/L and influent PFOS of 41 ± 18 ng/L to no reportable levels (Quinones and Snyder 2009).

In Point of Use (POU) studies in Minnesota GAC and GAC in combination with reverse osmosis were evaluated to determine their effectiveness to remove PFCs. These POU devices are typically under-sink for drinking water, but may also be designed for whole-house treatment, and are primarily used in residential settings treating domestic well water (groundwater). This comprehensive study found that GAC and GAC combined with reverse osmosis were effective to remove PFCs at manufacturer recommendations for water flow rate and volume throughput, although lower chain PFCs were removed at reduced rates using GAC alone (Olson and Paulson 2008). In cases where GAC was shown less effective, reverse osmosis enhanced PFC removal performance. In this study, GAC systems alone (without reverse osmosis) showed a loss of performance towards end of the carbon useful life, while combined GAC/reverse osmosis systems did not show a loss of performance at total throughput volumes. We expect that enhanced removal by reverse osmosis is likely due to added capability of reverse osmosis to remove charged ionic species, (inorganic and organic), such as the carboxylic PFCs, through both adsorption and electrostatic repulsion.

Advanced Oxidative Processes

Advanced oxidative processes such as chlorination, ozonation and UV peroxide, have been found effective to breakdown of organic compounds, including complex organics, but are not expected to provide significant removal of PFCs due to the strength of the C-F bond. No significant removal of PFCs was observed using UV and UV peroxide in a study by Arvaniti et al., 2013. One study showed only relatively modest PFOS removals between 10-50%, dependent on the oxidative process used (Ribeiro 2015).

Resin Adsoprtion/Ion Echange

Zeolites are widely used to purify water. One study found that PFOS adsorbs strongly to a NaY80 (Si/Al 80) zeolite, but other zeolites demonstrated poor adsorption (Ochoa-Herrera and Sierra-Alvarez 2008). This study also found that this zeolite adsorbed to PFOS at the same order

of magnitude as GAC, although overall GAC provided better PFOS removal. Anion exchange resins were also found effective for PFOS removal in wastewater in a study by Deng et. al., which also noted that sorption rates for PFOS were dependent on their polymer matrix and porosity (Deng et al., 2010). Ion exchange would not provide an equivalent level of PFC removal compared to GAC at equivalent cost.

Further Evaluation of RO versus GAC

Although both GAC and RO remove PFOA, PFOS, and other long chain PFCs to greater than 90%, RO has been shown in full scale and lab studies to remove PFOA to 99%. RO and NF also remove lower molecular weight short chained PFCs like PFBA and PFBS, found in water supplies. The recent Water Research Foundation (WRF) report of 2016 notes that "all PFASs were below the MRLs (maximum reporting limits) in the collected samples immediately following the RO systems, making this the most effective form of treatment evaluated in this study." The study systems, making this the most effective form of treatment evaluated in this study." The study included evaluation of GAC, anion exchange, oxidation, nanofiltration, and conventional water treatment methods (WRF 2016). The WRF study also notes that GAC and anion exchange "were less effective at removing shorter chain PFASs, whereas NF and RO were effective at removing even the smallest PFAS studied". RO and/or NF will assure removal of shorter chain PFBA and PFBS present.

Similar rejection of PFOS (>99%) was shown in a bench testing study of RO efficiency (Tang et al. 2006). WRF also notes in its 2016 report that nanofiltration membrane systems can be less costly and could prove to be just as capable of rejecting PFASs as RO in full-scale plants, as NF has been deemed potentially effective (> 95%) in bench-scale experiments using NF270 membranes (WRF 2016; Steinle-Darling and Reinhard 2008)."

Although GAC has been shown effective to remove PFOA, PFNA, and PFOS, often to > 90%, there are inconsistencies in GAC removal efficiency. In a study using GAC in Amsterdam, PFOA was not effectively removed, with a final mean GAC concentration of 5.3 ng/L (range 0.8 ng/L-9.4 ng/L) versus a mean influent PFOA concentration of 4.4 ng/L (range 3.8 ng/L-5.2 ng/L). In that study greater removal of PFOS and PFNA were achieved with a mean final water level of <0.23 ng/L and <0.24 ng/L, respectively, versus influent levels of 6.7 to 10 ng/L for PFOS and 0.5 to 0.8 ng/L for PFNA (Eschauzier et al., 2012). In a study of removal of PFOS and PFOA at a water treatment plant in Spain, treating about 100 million gallons per day of Llobregat surface river water to supply over 1 million inhabitants, RO removed PFOA to a mean of 2.1 ng/L in final water with influent raw water at a mean 6.9 ng/L. GAC removal resulted in a mean of 4.7 ng/L for PFOA in final water. This study found that PFOS was removed to a mean of 0.7 ng/L in final water, whereas GAC removed PFOS to a mean of 22 ng/L in final water, with raw water at 86 ng/L PFOS. Overall, this study found an efficiency of removal of 99% ± 1 for RO and 63% for GAC (Flores 2013).

In testing of 5 RO membranes and 3 NF membranes researchers found that rejection efficiencies (efficiency of removal) for RO membranes were >99% and for NF membranes

ranged from 90-99% (Tang et al., 2007).

PFC removal was studied at two water reclamation plants (treating domestic effluents as influent) in Southeast Queensland, Australia. One plant (plant A), treating about 2 million gallons per day, utilizes de-nitrification, ozonation, coagulation/flocculation, dissolved air flotation and sand filtration and biologically activated carbon filtration processes. The other plant (plant B), treating about 17 million gallons per day, utilizes coagulation/flocculation and sedimentation, ultra-filtration (UF), reverse osmosis (RO), advanced oxidation (peroxide with ultraviolet) and final stabilization and disinfection. In plant A using activated carbon PFCs were detected at all sampling points across the treatment train. In plant B using RO, PFCs were below reporting limits in samples taken from points after RO treatment (Thompson et al., 2010). Reporting limits (RL) ranged from 0.4 to 1.5 ng/L. At PFOA influent levels ranging from 15 to 27 ng/L, PFOA was removed to < RL to 1.4 ng/L in the RO effluent stage of plant B. PFOS was removed to <RL in the RO effluent stage with influent levels ranging from 23 to 39 ng/L. In this study activated carbon (biological) was ineffective to remove PFCs. However, this may have been due to the age of the carbon beds or short contact times.

Summary of Technology Effectiveness to Remove PFOS, PFOA, and PFNA

We conclude that the best available technology economically achievable to remove PFOS, PFOA, and PFNA from dilute aqueous streams at public water supplies is reverse osmosis (RO). In some cases GAC may be sequenced ahead of RO, and NF may potentially offer a substitute for RO. GAC followed by RO may be economically applied at Point-of-Use (POU) systems treating well water at residences or, in some cases, at residences receiving municipal drinking water with PFC contaminants. POU systems, in particular those using both GAC and RO, have been successful in Minnesota to remove PFCs, and allow redundancy in assuring continuous removal. Use of RO or GAC/RO is advantageous since additional health benefits may be derived by removal of disinfection byproducts (DBPs) produced during chlorination/disinfection of water supplies. RO is necessary to remove the haloacetic fraction of DBPs in these water supplies.

Given the nature of PFOA to cause long lasting adverse impacts on humans and the uncertainty inherent in toxicological studies to determine a protective MCL, best available technology should be used to assure health protection, irrespective of whether an MCL is 1 ng/L, 6 ng/L, or 14 ng/L.

Re: Health-Based Maximum Contaminant Level Support Document: Perfluorooctanoic Acid (PFOA)

Please find enclosed a technical analysis prepared by Fardin Oliaei, MPA, PhD, and Don Kriens, Sc.D., P.E. of Cambridge Environmental Consulting commissioned by Delaware Riverkeeper Network and submitted on behalf of the organization and its membership regarding the Support Document and recommendation by the Drinking Water Quality Institute for a **Health-Based Maximum Contaminant Level for Perfluorooctanoic Acid (PFOA)**. Also attached are two PDFs containing the Curriculum Vitae for Dr. Oliaei and for Don Kriens, Sc.D., P.E.

Delaware Riverkeeper Network submits these comments advocating that the public be protected from PFOA contamination and that New Jersey's drinking water be required to be treated to a safe level based on the best available scientific evidence.

We support all the recommendations and findings made by Dr. Oliaei and Cambridge Environmental Consulting in this technical analysis. We advocate that an appropriately protective MCL be recommended to and acted upon by the New Jersey Department of Environmental Protection and agree with Dr. Oliaei's finding that that the proposed drinking water MCL of 14 ng/L for PFOA based on increased relative liver weight is not adequately protective of all population segments. We support Dr. Oliaei's position that the standard may be developed based on an immunotoxic association in children or, alternatively, evidence of developmental effects shown in rodent studies. Both of these approaches provide more sensitive endpoints with quantitative data to develop an MCL, providing greater protection. We support Dr. Oliaei's analysis and final conclusion that the recommended MCL should be lowered to 1 ng/L, or alternatively, should be no higher than 6 ng/L.

Thank you for proposing a recommended MCL for PFOA, an action that is critically needed to remove this toxic compound from New Jersey's drinking water supplies.

Technical Analysis of NJDWQI Proposed Health-Based Maximum Contaminant Level (MCL) for Perfluorooctanoic Acid (PFOA)

by

Cambridge Environmental Consulting

Executive Summary

We conclude that the proposed drinking water MCL of 14 ng/L for PFOA based on increased relative liver weight is not adequately protective of all population segments. The criterion may be developed on the basis of epidemiologic evidence of a significant immunotoxic association in children or, alternatively, evidence of significant adverse developmental effects shown in rodent studies. Both of these offer more sensitive endpoints with quantitative data to develop an MCL to assure greater health protection. We calculate an approximate MCL of 0.5 ng/L based on the BMDL determined and the association found between immune suppression and serum PFOA levels in children as reported by Grandjean and Budtz-Jørgensen, or an approximate MCL of 1.0 ng/L based on the BMDL determined in the delayed mammary gland developmental effects in mice studies. Alternatively, we calculate a MCL of 6 ng/L for children group ages 1-6 using the increased liver weight endpoint, with exposure values we determined for mean weight and 90th percentile water intake in that group. We propose that NJDWQI lower the proposed MCL to 1.0 ng/L, consistent with the values found pursuant to the immunotoxic epidemiologic study and/or animal studies showing adverse developmental effects. Excluding use of these values the MCL should be no greater than 6 ng/L to assure protection of children.

Introduction

This is a summary of our analysis and evaluation of the proposed health based maximum contaminant level (MCL) for PFOA in drinking water developed by the New Jersey Drinking Water Quality Institute (NJDWQI), as described in its report Health-Based Maximum Contaminant Level Support Document: Perfluorooctanoic Acid (PFOA), dated June 27, 2016, hereinafter referred to as the NJDWQI Report.

The presence of PFOA in New Jersey water supplies is of great concern because high concentrations are found in groundwater and surface water within the Delaware River Watershed and other locations in New Jersey. According to NJDEP database as of January 2016, of 72 public water supplies (PWS) tested 47% or 66 PWS were found contaminated with PFOA at levels equal to or exceeding the reporting limit (5 ng/l). Thirty-two PWS or 45% had levels exceeding 10 ng/l, and 12 PWS or 17% had levels exceeding 40 ng/l (NJDWQl 2016). Water tested at these PWS includes both raw and finished water; negligible to no removal of PFOA is achieved in the conventional water treatment systems used at these PWS. The affected population was not listed although we would expect it to exceed 1 million. NJDEP has not

published studies of PFOA in private wells, however PFOA has been found at levels exceeding 40 ng/L (maximum >400 ng/L), in 59 private wells within 2 miles of a New Jersey industrial source (NJDWQI 2016 Report, DuPont, 2009).

Drinking water represents a significant portion of total human exposure to PFOA. The relative portion depends significantly upon the concentration of PFOA in drinking water. One study found that drinking water (at 9.66 ng/l) represented 24% of total exposure (Thompson et al 2011). Using NHANES 2003/2004 data, Lorber and Egeghy also determined a relative contribution of drinking water to total intake at 24%. They note that this rate is similar among adults and children (Lorber and Egeghy 2011). Others have found that drinking water represents a much higher portion of total exposure (Noorlander et al. 2011). A 20% contribution to total intake is used as a default value for relative source contribution (RSC) in this risk analyses.

PFOA exists predominantly in anionic form in drinking water sources. PFOA is non-volatile and therefore inhalation exposures to PFOA during showering and bathing and other domestic uses are negligible. PFOA does not cross the skin barrier and therefore PFOA is not absorbed into circulation via the skin, based on skin permeability of PFOA (Franko et al. 2012).

PFOA may escape water via aerosolization. In a laboratory study aerosols generated from deionized, fresh, and ocean waters spiked with PFO were found to have significantly higher concentrations of PFO than the parent water body, ≤ 80 times for ocean waters (McMurdo et al. 2008). Aerosols are produced by breaking waves on surface waters to generate air bubble beneath the surface which, when bursting at the surface, eject aerosol droplets into the atmosphere. This study also suggests that gas-phase evolution of PFOA from the aerosol-bound PFO into the atmosphere likely occurs due to the short aerosol-to-gas phase transfer half-life, about 7 seconds. Aerosol generation may also account for long-range air transport of PFOA, in addition to pathways of atmospheric transport of volatile precursors (8:2 FTOH) and transport of PFOA via the ocean.

Localized surface and groundwater PFOA contamination is primarily caused by wastewater discharges, air transport and deposition from PFOA emission sources, and groundwater plume migration. The extent of PFOA-laden aerosols via short-range air transport and potential direct exposure to humans is unknown but may help to explain, in part, PFOA concentrations in ground and surface waters in some locales proximate to factory sources, such as those found in Minnesota (Oliaei et al 2012).

We calculated that exposure to PFOA from drinking water source aerosols produced during typical showering conditions are likely to be negligible at a range of source water concentrations, based on equations we used in inhalation studies of aerosol particulates during showering (Cowen and Ollison, 2006; Zhou et al. 2010).

Calculation of MCL Using Quantitative Epidemiologic Data (Immunotoxicity)

The National Toxicology Program (NTP) supports a conclusion that PFOA alters human immune function (NTP 2016). A number of studies have shown PFOA immunotoxicity in that PFOA suppresses immune response. Four studies assessing associations with antibody concentrations following vaccination had prospective study designs that allowed temporality assessment. Among these, a prospective birth cohort study in Norway found strong evidence of decreased rubella-induced antibodies with increasing PFOA maternal serum concentrations in 99 pregnant women with a subsequent follow-up of 56 children at 3 years of age (Granum et al. 2013). Although no statistically significant associations were found with responses to vaccines for Influenza Type B or Influenza Type A H1N1, a large prospective cohort study of 411 adults in the mid-Ohio valley found decreasing antibody concentrations following Influenza A H3N2 vaccination (Looker et al., 2014). A large prospective cohort of 656 consecutive singleton births in the Faroe Islands with prospective follow-up of 587 cohort members at ages 5 and 7 years, found a strong association between serum PFC concentrations (PFOA and PFOS) and serum antibody concentrations against tetanus and diphtheria toxoids (Grandjean and Budtz-Jørgensen 2013).

The NJDWQI report acknowledged that "data from other human studies and toxicology studies provides support for biological plausibility of decreased immune system response to vaccines in humans" (NJDWQI Report 2016). The Report cites Fletcher et al. (2009), which "reported several statistically significant associations between several markers of immune function (decreased IgA; decreased IgE in females only; increased anti-nuclear antibody; decreased C-reactive protein) and serum PFOA levels in communities with drinking water exposure to PFOA in a C8 Science Panel status report" (NJDWQI 2016).

There is concordance with animal studies showing suppression of immune response. As noted in the NJDWQI report these include (in mice) decreased absolute and relative spleen and thymus weights, decreased thymocyte and splenocyte counts, decreased immunoglobulin response, and changes in total numbers and/or specific populations of lymphocytes in the spleen, thymus, peripheral blood, and bone marrow" (NJDWQI report).

NJDWQI notes that a "review of epidemiologic studies provides evidence of consistent findings among studies of decreased antibody concentrations following vaccination and PFOA. However, while there is epidemiologic evidence of temporality, evidence of an exposure-response is limited" (NJDWQI 2016). We disagree. We believe that where there is strong, significant epidemiologic evidence that includes quantitative data to enable derivation of a BMDL, such data should be taken into account in derivation of the MCL.

The Grandjean and Budtz-Jørgensen study represents the greatest sensitivity to PFOA thus studied, un-confounded by exposure to other chemical contaminants. In this study regression modeling of PFC concentrations (PFOA and PFOS) as independent variables along with potential confounders of sex, age, and booster type at age 5 and 7, with antibody concentrations as outcome, allowed determination of benchmark response (BMR) and benchmark dose (BMD).

The lower one-sided 95% CL (confidence limit) of the BMD, the BMDL (benchmark dose level), was determined in this study to be approximately 0.33 ng/ml for PFOA and 1.3 ng/ml for PFOS, based on the linear slope model of the regression. The study notes strong correlation between PFOS and PFOA, making mutual adjustment in the regression difficult. However, in spite of this the BMDL developed does provide a strong epidemiologic basis to develop a MCL.

Based on the immunotoxic effects shown in this study we propose that a 0.33 ng/ml BMDL for PFOA be used as a target human serum level. Assuming a serum:water ratio of 100:1 and an uncertainty factor (UF) of 10 to account for human variation in susceptibility, we calculate a MCL as follows:

MCL =
$$\frac{0.33 \text{ ng/ml}}{\text{UF } 10 \times 100 \text{ serum:water ratio}}$$
 = $\frac{330 \text{ ng/L}}{1000}$ = 0.33 ng/L (rounded to 0.5 ng/L)

Alternatively, the NJDWQI methodology uses a clearance factor of 0.00014 L/kg/day to apply to the Target Human Serum Level. Using that methodology, a BMDL of 0.3 ng/ml as the POD (point of departure) for RfD determination, and a UF of 10 for human variation in susceptibility to determine the Target Human Serum Level, the RfD is:

RfD =
$$330 \text{ ng/L} \times .00014 \text{ L/kg/day} = 0.0046 \text{ ng/kg/day}$$

UF 10

Using NJDWQI default adult exposure values of 70 kg body weight, 2 L/day water intake, and a relative source contribution of 0.2 the MCL is:

MCL =
$$0.0046 \text{ ng/kg/day} \times 70 \text{ kg} \times 0.2 = 0.032 \text{ ng/L}$$

2 L/day

Based on the above we propose that the MCL for PFOA be 0.5 ng/L.

Calculation of MCL based on Delayed Mammary Gland Development (Animal Studies)

Delayed mammary gland development in mice resulting from developmental exposures to PFOA is a sensitive endpoint. This toxicity effect has been shown in nine different studies (NJDWQI report 2016). Delayed mammary gland development is especially concerning since adverse effects including histological changes related to delayed mammary gland development persist into adulthood and become permanent. Several researchers indicate that delayed mammary gland growth may result in greater susceptibility to cancer later in life (Fenton 2006; Rudel et al., 2011; Fenton et al., 2012; Osborne et al. 2015). Others note that developmental exposures in sensitive time periods can result in increased risk of later disease or dysfunction (Heindel and Vandenberg, 2015). Mode of action is explained by Osborne: "Anything that changes the timing of mammary development will affect the timing of the presence of TEBs (terminal end buds), and therefore the window of susceptibility to

carcinogens. Late initiation of mammary development causes decreased longitudinal growth of the epithelium and fewer TEBs, and decreased alveolar budding at weaning. As development progresses, these glands may have more TEBs at puberty, because the pace of development is slower. It is hypothesized that factors that lengthen the period when TEBs are present lengthen the period during which the MG is susceptible to carcinogens" (Osborne et al., 2015).

NJDWQI acknowledged these studies, which may result in increased susceptibility to cancer later in life. The NJDWQI states that "The Health Effects Subcommittee chose not to use this (delayed mammary gland development) RfD as the basis for a recommended Health-based MCL, not because of uncertainty about the scientific validity of doing so, but rather because of lack of precedent for use of this endpoint as the primary basis for health-based criteria for environmental contaminants. Instead the Subcommittee arbitrarily applied an additional 10 UF to an unrelated endpoint (increased liver weight that forms the basis for their MCL derivation) to compensate for the more sensitive endpoint (delayed mammary gland development). This is confusing. Why not use the more sensitive endpoint for which adequate toxicity data already exists, including a BMDL, even if that endpoint has not previously been used, versus adding an additional uncertainty factor to an alternate endpoint to compensate for an uncertainty that is, in fact, known?

We propose that the MCL be determined using the sensitive endpoint BMDL for delayed mammary gland development, clearance factor, and default adult exposure values per NJDWQI analyses, as follows:

Summary of variables used and values

BMDL

POD of 22.9 ng/ml (22,900 ng/L)

total UF

30 (10 human variation, 3 animal-to-human extrapolation)

RSC

0.20

clearance factor

0.00014 L/Kg/day

default adult body weight 70 kg per NJDWQl report

default adult intake

2.0 L per NJDWQl report

RfD = $22,900 \text{ ng/L} \times 0.00014 \text{ L/kg/day} = 0.107 \text{ ng/kg/day}$ 30 UF

MCL = $0.107 \text{ ng/kg/day } \times 70 \text{ kg } \times 0.2 = 0.75 \text{ ng/L} \text{ (rounded to 1 ng/L)}$ 2 L/day

Based on the above we propose that the MCL for PFOA be 1 ng/L.

Children, PFOA Exposure, and Use of Adult Default Exposure Values

There is evidence that young children are exposed to greater levels of PFOA than adults. This

may occur because of age-specific behaviors such as hand-to-mouth behaviors resulting in greater ingestion of house particulates, and more time spent on floors with treated carpets. Using NHANES data, Lorber and Egeghy found that incidental ingestion of dust is far less important among adults than among children (Lorber and Egeghy 2011). Children's dust intakes are highly variable due to the distribution of dust PFOA concentrations in homes. The 95th percentile intake from dust ingestion is about three times the intake from food ingestion (Lorber and Egeghy 2011).

Peak serum PFOA concentrations occur during the first year of life, in part due to "off-loading" from the mother at birth. As noted in NJDWQI report, levels remain elevated for at least several additional years. Blood serum levels have been found to be higher in children. Higher serum levels were observed in children ages 2-5 versus older children and adults in Little Hocking, Ohio residents who have been exposed to PFOA in drinking water (Emmet et al 2006). Toxicity effects to children during this developmental period may persist into adulthood and become permanent.

Children therefore represent a special case. They have greater drinking water and food consumption on a body weight basis. Using adult default exposure values is inappropriate since a priori use of adult default values for body weight and water intake omits protection to children, the population's most vulnerable exposure group. Calculation of a MCL using adult default values results in a RfD to children (age group 1-6) that significantly exceeds that deemed allowable by NJDWQI based on the increased liver weight toxicity endpoint.

Although the MCL should be based on human immunotoxicity and/or the delayed mammary gland development shown in test animals, as calculated above, we believe that at a minimum MCL calculations using increased liver weight as an endpoint should be based on children exposure values for body weight and drinking water intakes. Using children group ages 1-6 we determined the MCL as follows:

Summary of variables used and values

BMDL

POD of 4351 ng/ml (4,351,000 ng/L)

CUF

300 (10 human variation, 3 animal-to-human extrapolation, 10 for

delayed mammary gland development

RSC

0.20

Children body weight^a

16.8 kg

Children intakeb

0.69 L/day mean, 1.19 L/day 90th percentile

Children Group (age 1-6)

 $RfD = 4.351,000 \text{ ng/L} \times 0.00014 \text{ L/kg/day} = 2.03 \text{ ng/kg/day}$

300 UF

MCL = $\frac{2 \text{ ng/kg/day} \times 16.8 \text{ kg} \times 0.2}{1.19 \text{ L/day}}$ = 5.65 ng/L (rounded to 6 ng/L)

a. These values were determined using EPA 2011 Exposure Factor Handbook data, taking smaller increments of age groups and gender, combined by weighting the means of group increments, and pooling variances to determine means and standard deviations.)

b. Following EPA's default criteria of 90^{th} percentile distribution of water intake, we found a 1.19 L/day water intake rate for children 1-6 at the 90^{th} percentile, based on derivation of a lognormal distribution of water intake for this combined age group, shown in the graph below.

Lognormal Distribution of Water Intakes for Children Group Ages 1-6

Based on the above the MCL for PFOA should be 6 ng/L.

Conclusion

NJDWQI's Health Effects Subcommittee's work in developing a MCL for PFOA demonstrates a considerably sounder scientific basis than EPA's recent drinking water advisory for PFOA, where a 70 ng/L MCL is developed (USEPA 2016). However, NJDWQI's reliance upon Increased Relative Liver Weight in animal studies as an endpoint to develop a RfD disregards more sensitive toxicity endpoints. We believe that animal studies showing significant delayed mammary gland development are sufficient and appropriate to use in the MCL determination, irrespective of whether there is absence of precedence, where benchmark dose modeling allows calculation of an approximate MCL of 1 ng/L. Substantial epidemiological evidence showing a range of toxic effects should also be taken into account versus reliance solely upon animal studies. One such study, the Immunotoxicity study by Grandjean and Budtz-Jørgensen 2013 showing a significant association between PFOA and suppression of antibody responses in children, provides benchmark dose response data to calculate a MCL of ≤1 ng/L.

In addition, the proposed MCL of 14 ng/l calculated using adult default values for body weight results in a PFOA dose to children (ages 1-6) that is 50% higher at mean water intake levels, and 2% times higher at 90^{th} percentile water intake levels, than the reference dose (RfD) allowed to assure that serum levels remain below a protective maximum target level. Thus, the proposed

MCL of 14 ng/L using default adult exposure values is not protective of all age groups. This is concerning since, based on animal developmental studies that likely relate to humans, toxic effects from PFOA exposures in early childhood may persist into adulthood and could result in more profound disease in later life.

Absent lowering the proposed MCL to 1 ng/L, the MCL should be no higher than 6 ng/L.

Re: Health-Based Maximum Contaminant Level Support Document: Perfluorooctane Sulfonate (PFOS) 11 (CAS #: 1763-23-1; Chemical Formula: C8HF17O3S)

Please find enclosed a technical analysis prepared by Fardin Oliaei, MPA, PhD, and Don Kriens, Sc.D., P.E. of Cambridge Environmental Consulting commissioned by Delaware Riverkeeper Network and submitted on behalf of this organization and its membership regarding the Support Document and recommendation by the New Jersey Drinking Water Quality Institute (NJDWQI) for a **Health-Based Maximum Contaminant** Level for Perfluoroctane Sulfonate (PFOS). Also attached are two PDFs containing the Curriculum Vitae for Dr. Oliaei and for Don Kriens, Sc.D., P.E.

Delaware Riverkeeper Network submits these comments advocating that the public be protected from PFOS contamination and that New Jersey's drinking water be required to be treated to a safe level based on the best available scientific evidence.

We support all the recommendations and findings made by Dr. Oliaei and Don Kriens of Cambridge Environmental Consulting in this technical analysis. We advocate that an appropriately protective MCL be recommended to and acted upon by the New Jersey Department of Environmental Protection and agree with Cambridge Environmental Consulting's finding that that the NJDWQI's recommended drinking water MCL of 13 ng/L for PFOS is not adequately protective of all population segments. We support Cambridge Environmental Consulting's position that the standard should be calculated based on children's exposure values. We agree that it is of utmost importance to assure protection of children's health since the developing fetus, infants, and young children are particularly sensitive to PFOS exposure during early sensitive periods. As explained by Dr. Oliaei and Don Kriens, even at very low doses, early life exposure of children to PFOS may affect risk for disease later in life. We support Cambridge Environmental Consulting's analysis and final conclusion that the recommended MCL should be lowered to 5 ng/L.

DELAWARE RIVERKEEPER NETWORK 925 Canal Street, Suite 3701 Bristol, PA 19007 Office: (215) 369-1188 fax: (215)369-1181 drn@delawareriverkeeper.org www.delawareriverkeeper.org We also support Cambridge Environmental Consulting's conclusion that when found combined with PFOA in water, the combination of PFOS and PFOA concentrations in water supplies should be no higher than 13 ng/L.

Thank you for proposing a recommended MCL for PFOS, an action that is critically needed to remove this toxic compound from New Jersey's drinking water supplies.

Sincerely,

Maya van Rossum the Delaware Riverkeeper

Tracy Carluccio Deputy Director

Tray Corraio

Attached: Technical Analysis of New Jersey's Proposed Health-Based Maximum Contaminant Level (MCL) for Perfluorooctane Sulfonate (PFOS), Fardin Oliaei, Ph.D. and Don L. Kriens, Sc.D., Cambridge Environmental Consulting, submitted January 2018.

Technical Analysis of New Jersey's Proposed Health-Based Maximum Contaminant Level (MCL) for Perfluorooctane Sulfonate (PFOS)

by

Fardin Oliaei, Ph.D. and Don L. Kriens, Sc.D. Cambridge Environmental Consulting submitted January 2018

Executive Summary

The RfD (reference dose) for PFOS (perfuorooctane sulfonate) derived by the NJDWQI (New Jersey Drinking Water Quality Institute) is the most stringent and protective in the U.S., based on a rigorous analysis of all available PFOS animal and epidemiologic toxicological studies. However, in its use of adult default exposure values to determine a maximum contaminant level (MCL), younger children would not be protected since younger children dose intakes would exceed the allowable RfD. This is disconcerting since existing PFOS serum levels in children in the normal population are already within or near the serum PFOS levels associated with immunotoxic effects found in epidemiologic studies. In addition, other toxic effects found associated with children and PFOS exposure may lead to increased potential for later disease manifestation. It is essential, therefore, that the NJDWQI depart from the typical use of adult default exposure values and use children's values. Using appropriate children exposure values, we recommend a *MCL for PFOS of 5 ng/L*.

Alternatively, we recommend a MCL such that the combination of PFOS and PFOA concentrations in water supplies be no higher than 13 ng/L, MCL [PFOA + PFOS] \leq 13 ng/L.

Introduction

The presence of PFOS and PFOA (perfluoro-octanoic acid) in New Jersey is of public health concern because relatively high concentrations have been found in public water supplies (PWS), in some instances at levels greater than the existing 14 ng/l MCL for PFOA and the proposed 13 ng/l MCL for PFOS. Ten of 80 PWS tested by the New Jersey DEP (Department of Environmental Protection) had PFOS at levels ≥ 20 ng/l with 7 PWS containing PFOS at levels exceeding 40 ng/l (NJDEP 2017). Testing of 175 New Jersey PWS, including 165 large community systems and 10 small community systems completed under the UCMR3, found 6 PWS with PFOS levels exceeding 40 ng/L and 18 PWS with PFOA levels exceeding 20 ng/L (UCMR3 2017, NJDWQl 2017). Ingestion of any level of PFOS and PFOA contaminated water could further increase residents' PFOS blood serum levels beyond that already found in epidemiologic studies to be associated with adverse health effects (immunotoxicity) in the general U.S. population.

A large number of animal studies indicate a wide range of PFOS toxicity effects. These include decreased body weight, increased liver weight with microscopic lesions in monkeys and rats, increased incidence of hepatocellular adenomas in rats, developmental effects on rats and mice including neonatal mortality, decreased gestation length, lower birth weights, and developmental delays. For post-gestation and lactational exposure these include: developmental neurotoxicity, changes in thyroid and reproductive hormones, altered lipid and glucose metabolism, and decreased immune function (USEPA 2016b).

Among non-cancer endpoints the NJDWQI concludes that, for adult animals, the most sensitive endpoints (lowest LOAELs based on serum PFOS concentrations) are described in 9 studies and include: "endocrine/metabolic effects (e.g., decreases in thyroid hormone and increased incidence of thyroid follicular cell adenomas), changes in immune parameters (e.g., increased relative number of macrophages and decreased plaque forming cell response), and increased liver weight and liver histopathology" (NJDWQI 2017). For post-natal or gestational exposures, NJDWQI concludes the most sensitive non-cancer endpoints (lowest LOAELs based on serum PFOS concentrations) are described in 11 studies and include: "decreased body weight, changes in endocrine/metabolic parameters (i.e., fasting levels of serum glucose and insulin, markers of insulin resistance, and thyroid hormone levels), increased liver weight, changes in lung morphology, and increased mortality" (NJDWQI 2017).

NJDWQI examined these 20 toxic endpoints in terms of the timing of biological significance and suitability for dose-response analysis, and determined 4 endpoints suitable to calculate a (POD) point of departure. The immunotoxic effect shown in the Dong et al. (2009) study was chosen as the most sensitive POD (point of departure) at 674 ng/ml.

The immunotoxic endpoint chosen to develop an MCL based on decreased plaque forming cell response, a predictor of immunosuppression, in animal studies is supported by epidemiologic studies that found associations between PFOS and PFOA blood serum levels in humans and decreases in immune function.

A study by Grandjean and Budtz-Jørgensen (2013) found an association between increases in serum PFOS and PFOA levels and decreases in serum antibody concentrations against tetanus and diphtheria toxoids. In this study regression modeling of PFOA and PFOS concentrations as independent variables along with potential confounders of sex, age, and booster type at age 5 and 7, with antibody concentrations as outcome, allowed determination of benchmark response (BMR) and benchmark dose (BMD). The lower one-sided 95% confidence limit of the BMD, the BMDL (benchmark dose level), was determined in this study to be approximately 0.33 ng/ml for PFOA and 1.3 ng/ml for PFOS, based on the linear slope model of the regression. The study notes strong correlation between PFOS and PFOA, making mutual adjustment in the regression difficult. However, the BMDL developed provides a strong epidemiologic basis using an immunosuppression endpoint to develop a MCL.

A study in Norway evaluated the effect of prenatal exposure to PFAS (perfluoroalkyl substances) on responses to pediatric vaccines and immune-related health outcomes in

children up to 3 years of age (Granum et al. 2013). In this study blood samples were taken from the mothers at time of delivery and children at 3 years age. The study found an inverse association between the level of anti-rubella antibodies in the children's serum at age 3 years and the concentrations of four PFAS compounds (PFOS, PFOA, PFNA, and PFHxS). The strength of the association between rubella antibody-levels and PFAS concentrations were PFNA>PFOA>PFH_xS>PFOS.

A cross-sectional study of 1191 children 12-19 years old using NHANES data (1999-2000 and 2003-2004) found that increased exposure to several PFAS compounds was associated with lower levels of mumps and rubella antibody concentrations, especially among seropositive individuals (Stein et al. 2016). This study found that a doubling of PFOS serum concentration was associated with a 7.4% (95% Cl: -12.8, -1.7) decrease in mumps antibodies. A doubling of PFOS serum concentration was also associated with a 13.3% decrease in rubella antibodies; this association occurred among seropositive individuals. Decreases in rubella antibodies were also found to be associated with PFOA and PFH_xS. The authors found that children with higher PFOS levels were less likely to be sensitized to allergens, but children with higher PFOS levels were more likely to be sensitized to mold (IQR OR 1.33, 95% Cl: 1.06, 1.69).

A small study in Denmark evaluated reduced antibody responses to perfluorochemical exposures (Kielsen et al. 20016). Twelve adults were boosted with tetanus and diphtheria toxoids with antibody responses and followed in a subsequent one-month period. Participants had been vaccinated with diphtheria and tetanus toxoids in childhood, but no boosters had been received within the last 5 years. The study found that at a doubling of PFOS exposure, based on serum obtained from participants 10 days post-vaccination, the relative increase in the diphtheria antibody concentration decreased by an average of about 12%, p = 0.044. Significant diptheria antibody concentration reductions were also found for PFNA, PFDA, PFU_nDA, and PFD_oDA.

A study of 411 adults in the mid Ohio region of Ohio and West Virginia, where the drinking water supply had been contaminated with PFOA (Dupont plant), evaluated antibody response and PFOS and PFOA levels in blood serum following vaccination with influenza vaccine. The study found that elevated PFOA serum concentrations were "associated with reduced antibody titer rise, particularly to A/H3N2 influenza virus, and an increased risk of not attaining the antibody threshold considered to offer long-term protection" (Looker et al. 2014). However, in this study no association was found between PFOS serum levels and reductions in antibody rise.

The National Toxicology Program concluded that "exposure to PFOS is *presumed to be an immune hazard to humans* based on a high level of evidence that PFOS suppressed the antibody response from animal studies and a moderate level of evidence from studies in humans". NTP also concludes that "PFOS is suspected to suppress infectious disease resistance and NK cell activity in humans, and these conclusions are based on moderate level of evidence from animal studies and low or inadequate level of evidence from human studies" (NTP 2016).

Human epidemiologic data have current limitations and are not used as a quantitative basis for a health-based RfD and MCL. However, a RfD based on quantitative epidemiologic data for an immunotoxic effect should be taken into account. In our review of the New Jersey 2016 proposed standard for PFOA we derived a MCL based on the Grandjean and Budtz-Jørgensen (2013) study where benchmark calculations based on regression modeling enabled a determination of a BMDL. Based on that study's BMDL we calculated a 0.03 MCL for PFOA (Oliaei and Kriens 2016). Using the same methodology, we derive a MCL for PFOS as follows:

The lower one-sided 95% confidence limit of the BMD, the BMDL (benchmark dose level) determined in the Grandjean and Budtz-Jørgensen (2013) study, is approximately 1.3 ng/ml for PFOS, based on the linear slope model of the regression. Based on the immunotoxic effects shown in this study we propose a 1.3 ng/ml BMDL for PFOS as the target human serum level. An uncertainty factor of 10 for human variation in susceptibility is applied. A clearance factor of 8.1×10^{-5} L/kg/day derived by USEPA for PFOS (USEPA 2016b) is applied to the target human serum Level to calculate an RfD.

RfD =
$$\frac{1.3 \text{ ng/ml} \times 1000 \text{ ml/L}}{\text{UF } 10} \times 8.1 \times 10^{-5} \text{ L/kg/day} = 0.01 \text{ ng/kg/day}$$

Using NJDWQI default adult exposure values of 70 kg body weight, 2 L/day water intake, and a relative source contribution of 0.2, the MCL is:

$$MCL = \frac{0.01 \text{ ng/kg/day} \times 70 \text{ kg}}{2 \text{ L/day}} \times 0.2 \text{ RSC} = 0.07 \text{ ng/L} \text{ (round to 0.1 ng/L)}$$

Absent application of epidemiologic data, NJWQl's rigorous methodology and criteria used to select a BMDL, or NOAEL if applicable, is scientifically sound and conservative. Of the 4 final studies chosen by NJWQl for dose-response modeling, the Dong et al 2009 study of decreased plaque forming cell response, predictive of immunotoxicity, resulted in the lowest (most sensitive) point of departure (POD). As discussed in the report, the NOAEL of the study was used as the POD, or 674 ng/L, since BMDS software modeling would not calculate a BMDL for this study's dose-response data (NJDWQl 2017). After application of uncertainty factors the target human serum level calculated was the lowest among the 4 final studies, and resulted in the lowest RfD of 1.8 ng/kg/day.

This RfD is considerably more protective than the USEPA RfD of 20 ng/kg/day based on animal developmental effects (e.g. decreased pup body weight) (USEPA 2016b). However, because of potential increased susceptibility during pregnancy and lactation EPA used drinking water intake and body weight exposure values at the 90% distribution for lactating women, moderating the calculation (versus use of adult default weight and intake) to 70 ng/l for a lifetime health advisory (HA) or "MCL" for this target population.

Although the RfD determined by NJDWQI is a significant departure from the much less

protective RfD of 20 ng/kg/day developed by USEPA, we disagree with the UF (uncertainty factor) used to determine the target human serum level. NJDWQI applied a UF of unity (1.0) for sub-chronic versus chronic testing used in Dong et al (2009) even though this study of 60 days is of sub-chronic duration. Sub-chronic duration is > 30 day to \leq 90 days. A UF of 10 is normally applied when sub-chronic is used instead of chronic testing to estimate a NOAEL.

NJDWQI asserts that an uncertainty factor to extrapolate sub-chronic to chronic is not needed because the immunotoxicity studies of sub-chronic duration did not show a greater effect (response) at longer duration (but within the sub-chronic duration period) among the three studies reviewed. NJDWQI notes that for the same PFOS serum concentration of 1 x 10⁵ ng/ml, plaque forming cell response decreased by the same 60% in two studies despite the difference in duration between these two studies, Zheng et al (2009) at 7 days duration and Dong et al (2009) at 60 days duration. NJDWQI asserts, therefore, that the decrease in plaque forming cell response does not progress at longer exposure duration. Although suggestive of a lack of progression over time, these tests are of very short duration (7-60 days) and would not fully explain whether this premise holds true at longer chronic durations of 6 months or more. Further, the mechanistic basis for the immunotoxic effect of PFOS is unknown, and whether further long-term exposures accelerate this effect.

Omission of a UF for sub-chronic-to-chronic in risk assessment should not be done on the basis of results taken solely from short term studies, especially without an understanding of the mechanism of toxicity. A UF should be applied. In lieu of some (limited) evidence of no increase in effect in dose-response between the 7-day and 60-day short-term sub-chronic studies applying a UF of 3 versus 10 is reasonable.

As indicated by NJDWQI, "serum PFOS levels in the general U.S. population are currently near or within the range of central tendency serum PFOS levels in the studies that found associations with decreased immune response (NJDWQI 2017). Median and 95% serum PFOS concentrations are 5.2 ng/ml and 19 ng/ml, respectively, in the general U.S. population (CDC-NHANES 2017). Decreases in vaccine response were found at serum levels 6 – 27 ng/ml (Grandjean et al. 2012; Granum et al. 2013; Kielsen et al. 2016; Stein et al., 2016), within the range of serum levels in the general population. Therefore, contribution of any additional PFOS from exposure to contaminated drinking water, irrespective of the MCL level chosen, may be inadequate to assure protection for these toxicity effects (immunotoxicity), especially in sensitive individuals and vulnerable segments like infants and children. This uncertainty is broadly reflected in applying UFs to calculate MCLs.

Derivation of RfD and MCL - Adding an Uncertainty Factor to Adjust Sub-chronic to Chronic

A UF of 3 should be applied to extrapolate from sub-chronic to chronic testing in the Dong et al. (2009) study, to calculate a RfD and MCL, as follows:

A UF_{human} of 10 was used to account for increased sensitivity in sensitive sub-populations versus the average human population, and for general physiological and metabolic variation within the human population. A UF of 3 was used to account for interspecies (rodent to human) toxicodynamic differences. No UF is needed for toxicokinetic differences since the POD (point of departure), in this case the NOAEL, is based on blood serum PFOS levels. A UF of 3 is applied to estimate the NOAEL for chronic testing from sub-chronic testing used. Since individual UFs are as log-units the product of 3 x 3 is taken as 10. Therefore, the total UF applied is 100.

Target Human Serum Level = POD (NOAEL)
$$\frac{674 \text{ ng/ml}}{\text{UF } 100}$$
 = 6.74 ng/ml

The RfD (reference dose) is calculated as: target human serum level x clearance factor, where the clearance factor is the constant 1.8×10^{-5} derived by USEPA (EPA 2016b).

Reference dose (RfD) = 6.74 ng/ml x 1000ml/L x .000081 L/kg/day = 0.55 ng/kg/day

Summary of variables

674 ng/ml NOAEL (POD)

100 (10 UF_{human}, 3UF_{subcronic-chronic}, 3UF interspecises toxicodynamic) total UF

6.74 ng/ml Target human serum level

0.20 RSC

0.000081 L/Kg/day

clearance factor per NJDWQI 70 kg default adult body weight 2.0 L/day per NJDWQI default adult water intake

To compare with NJDWQI in its derivation, the MCL is calculated using adult default exposure values of weight and intake:

MCL =
$$0.55 \text{ ng/kg/day} \times 70 \text{ kg} \times 0.2$$
 = 3.85 ng/L (rounded to 4 ng/L)
2 L/day

Adjusting the total UF to 100, the MCL calculated using NJDWQI variables should be 4 ng/L.

Children Exposure and Risk

There is evidence that young children are exposed to differential intakes of PFOS and PFOA because of age-specific behaviors, such as hand-to-mouth behavior, resulting in greater ingestion of house dust and dust on surfaces/products containing perfluorochemicals such as upholstered furniture, clothing, bedding, automobile fabrics, and carpets. These exposures are generally in addition to normal PFOS exposures from food and water, packaging, and a range of consumer products.

Using NHANES data, Lorber and Egeghy found that incidental ingestion of dust is far less important among adults than children (Lorber and Egeghy 2011). Children dust intakes are highly variable due to the distribution of dust PFOA concentrations in homes; the 95th percentile intake from dust ingestion is about three times the intake from food ingestion (Lorber and Egeghy 2011). In another study by Egeghy and Lorber, the authors estimated that under typical exposure conditions, where exposure media concentrations are representative of background conditions, the median PFOS intake (sum of the median route-specific intakes) for 2-year-old children under typical exposure conditions was 50 ng/day (Egeghy and Lorber 2011). In the typical scenario for 2-year olds the contribution from ingested dust and ingested water were found to be nearly the same at 36% and 42%, respectively. Alternatively, for adults the contributions to PFOS daily intakes were much different, 6% for dust ingestion and 72% for food.

Under a typical scenario Egeghy and Lorber estimated a median total PFOS intake at 160 ng/day for adults. Under a contaminated environment scenario (contaminated water supply) they estimate median total PFOS intakes of 640 ng/day in 2-year olds and 2200 ng/day in adults. In either the typical scenario or a contaminated water scenario the authors estimated that the contribution of water to total PFOS intake is about the same in adults as in 2-year olds, about 20%. Using the authors median PFOS intake data and median weight for 2-year olds of about 13 kg (Table 8-12, Exposure Factors Handbook 2011), we calculate the median PFOS daily dose to 2-year olds at 3.85 ng/kg/day, and the median daily PFOS dose to adults (using a default 70 kg adult weight) at 2.29 ng/kg/day under the typical scenario. The 2-year old children PFOS daily exposure dose is therefore about 70% higher than adults. Both adults and children (2-year olds) median daily dose under the typical exposure scenario would exceed the allowable reference dose (RfD) of 1.8 ng/kg/day proposed by NJDWQI for PFOS, double the proposed RfD in 2-year olds.

In addition to greater environmental exposures than adults, children are burdened with PFOS at birth. "Evidence shows that PFOS is distributed within the body and can be transferred from pregnant women to their unborn children and offspring" (USEPA 2016b). PFOS has been quantified in umbilical cord blood, suggesting maternal transfer (Apelberg et al. 2007; Cariou et al. 2015; Tao et al. 2008; Völkel et al. 2008; Von Ehrenstein et al. 2009; USEPA 2016b). One study found PFOS at a mean of 1.28 ng/ml in 99 of 100 samples of cord blood (Cariou et al. 2015).

PFOS is also transferred to children via breast milk. Cariou et al. 2015 found PFOS in 82% of breast milk samples at a mean concentration of 0.04 ng/ml. In a study of 70 human breast milk samples in patients from Germany and Hungary PFOS concentrations ranged from 0.028 to .309 ng/ml (Völkel et al. 2008; USEPA 2016b). PFOS transfer to infants during breast feeding lowers the mother's PFOS blood serum levels. In a study by Mondal et al. (2014) of 633 women and 49 infants each month of breast feeding was found to lower maternal serum PFOS levels by 3%

and increase infant serum levels by 4%. Using the Cariou et al. (2015) mean breast milk PFOS concentration of 0.04 ng/ml and an upper percentile daily milk intake of 951 ml/day (table 15-3, USEPA 2008), we calculated daily PFOS intake from breast milk to breast fed infants 0 < 1 years at about 38 ng/day. Based on a 90th percentile body weight of 10.8 kg for infants 6 < 12 months age (table 8-3 USEPA 2008), the daily dose intake for this infant group of 0 < 1 years from breast milk is estimated at 3.5 ng/kg/day.

In summary, age-specific behaviors (e.g. hand-to-mouth) and exposures from placental transfer and breastfeeding, in addition to normal exposures from ingested water and food, increase the PFOS body burdens in young children.

Children Toxicity Studies

Epidemiologic studies have shown many associations between PFOS and PFOA exposure and health effects in children. A systematic review by Rappazzo et al. (2017) summarized the epidemiologic evidence (literature) for relationship between prenatal/childhood perfluorochemical exposure and health outcomes in children. They conclude: "there is evidence for positive associations between PFAS (perfluoroalkyl substances) and dyslipidemia, immunity (including vaccine response and asthma), renal function, and age at menarche", as described below (Rappazzo et al. 2017).

A study by Geiger et al. (2014) in adolescents from NHANES data, found increases in PFOA, PFOS, or total PFAS serum concentrations positively associated with high total cholesterol (>170 mg/dL) and high LDL-C. Results in a study of 12,476 children and adolescents found that PFOA was significantly associated with increased total cholesterol and LDL-C, and PFOS was significantly associated with increased total cholesterol, HDL-C, and LDL-C (Frisbee et al. 2010). Several other studies support dyslipidemia effects from exposure to PFCs in children (Rappazzo et al. 2017).

Delayed onset of puberty has been associated with altered risk of adult disease: diabetes mellitus, heart disease, bone disease, substance abuse, and asthma" (Rappazzo et al 2017). A C8 cross-sectional analysis of 3076 boys and 2931 girls found later age of puberty in both boys and girls associated with serum PFOS and PFOA levels (Lopez-Espinosa et al. 2011). For boys in that study "there was a relationship of reduced odds of reached puberty (raised testosterone) with increasing PFOS (delay of 190 days between the highest and lowest quartile)". In girls, "higher concentrations of PFOA or PFOS were associated with reduced odds of postmenarche (130 and 138 days of delay, respectively)". Delayed onset of puberty associated with PFOS and PFOA levels in epidemiologic studies is supported by animal studies. For example, PFOA was found to cause delayed mammary gland development in female mice offspring (White et al. 2011).

A limited number of studies have shown associations between renal function and serum PFC levels. Decrements in estimated glomerular filtration rate (eGFR) were found to be associated with increases in PFOA and PFOS concentrations in a large community study of 9660 children

age 1<18 years (Watkins et al. 2013). The study population was children and adolescents highly exposed to PFOA from contaminated water supplies, but exposed to levels typical of PFOS, PFNA, and PFHxS in the normal population. Another cross-sectional analyses of NHANES 2003-2010 data of 1960 adolescents aged 12-19 years found PFOS and PFOA associated with a reduction in kidney function and increased uric acid levels (Kataria et al. 2015). The authors found that adolescents in the highest PFOA and PFOS quartile had a lower eGFR (estimated glomerular filtration), 6.84 mL/min/1.73 m² (95 % CI: 2.19 to 11.48) and 9.69 mL/min/1.73 m² (95 % CI: -4.59 to 14.78), respectively, compared to the lowest quartile. However, the authors note that reverse causality and residual confounding could explain their findings.

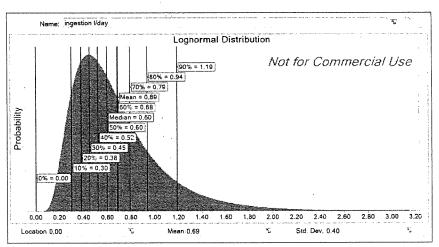

As described in the Introduction, three epidemiologic studies found suppression of vaccine-mediated antibody response to be associated with PFOS and PFOA exposure in children. The study by Grandjean and Budtz-Jørgensen (2013) found an association between increases in serum PFOS and PFOA levels and decreases in serum antibody concentrations against tetanus and diphtheria toxoids in young children (follow-up of a Faroese birth cohort). A study in Norway of 99 participants found an inverse association between the level of anti-rubella antibodies in children's serum at age 3 years and the concentrations of PFOS, PFOA, PFNA, and PFHxS (Granum et al. 2013). A recent large cross-sectional study by Stein et al (2016) of 1191 children 12-19 years old using NHANES data (1999-2000 and 2003-2004) found that a doubling of PFOS serum concentration was associated with a 7.4% (95% CI: -12.8, -1.7) decrease in mumps antibodies. A doubling of PFOS serum concentration was also associated with a 13.3% decrease in rubella antibodies; this association occurred among seropositive individuals (Stein et al. 2016).

PFOS serum levels in children associated with these immunosuppressive effects, found in these studies, are within or close to the PFOS serum levels found in the normal population.

Calculation of MCL Based on Children-Specific Exposure Variables

Some of the PFOS toxic endpoints to children have lasting effects and may subject children to later disease development. Deriving a MCL based on adult weights and water intakes results in a RfD imposed on children in excess of the maximum allowable 1.8 ng/kg/day. The uncertainty factor for sensitivity in the human population applied in the derivation accounts only for human variability in sensitivity to effect. To assure protection of children it is important that children-specific weight and water intake exposure values be used in the MCL calculation.

Body weight and water intakes of children ages 1-6 are used herein to determine a MCL. We use a mean body weight for this group of 16.8 kg and water intakes of 0.69 L/day mean, 1.19 L/day 90th percentile. Mean weight for the group 1-6 were determined using EPA 2011 Exposure Factor Handbook data for these ages, taking smaller increments of age groups and gender, combined by weighting the means of group increments, and pooling variances to determine means and standard deviations. We determined a 1.19 L/day composite water intake rate for children 1-6 at the 90th percentile, based on the lognormal distribution of water intakes for this combined age group, shown in the graph below.

Lognormal Distribution of Water Intakes for Children Group Ages 1-6

To compare the difference in MCLs derived by NJDWQI with that derived herein using children weight and water intakes, we use the same RfD of 1.8 ng/kg/day derived by NJDWQI (which excludes applying the uncertainty factor of 3 we used to estimate NOAEL chronic from subchronic testing).

Summary of variables used and values

RfD 1.8 ng/kg/day

RSC 0.20 children body weight 16.8 kg

children intake 1.19 L/day 90th percentile

Children Group (age 1-6)

 $MCL = \underline{1.8 \text{ ng/kg/day}} \times \underline{16.8 \text{ kg}} \times 0.2 \text{ RSC} = 5.08 \text{ ng/L} \text{ (round to 5 ng/L)}$ 1.19 L/day

(Using a mean water intake of 0.69 L/day results in a MCL of 8.8 ng/L)

The MCL for PFOS should be 5 ng/l.

If a UF of 3 to estimate chronic NOAEL from sub-chronic is included the MCL becomes:

MCL =
$$0.55 \text{ ng/kg/day} \times 16.8 \text{ kg} \times 0.2 \text{ RSC} = 1.55 \text{ ng/L}$$
 (round to 2 ng/L)
1.19 L/day

Other states have recognized children and infants as a more vulnerable population segment. Vermont used a 95th percentile body weight-adjusted water intake rate of 0.175 L/kg/day for the first year of life in its MCL calculation to determine a MCL of 20 ng/l. The MCL is applied as a

sum combination, $[PFOS + PFOA] \le 20 \text{ ng/l}$ (Vermont 2016). In 2017 the Minnesota Department of Health (MDH) updated its earlier Health Risk Limit (HRL) for PFOS in drinking water. MDH used the USEPA RfD of 20 ng/kg/day based on animal developmental effects but incorporated a database uncertainty factor of 3 in recognition of immunotoxicity shown in animal studies. This resulted in a RfD of 5.1 ng/kg/day. MDH modeled two scenarios and found a breast-fed infant exposure scenario as most limiting, and determined a PFOS limit of 27 ng/L (MDH 2017).

Conclusion

NJDWQI's evaluation of animal and epidemiologic PFOS toxicity studies was comprehensive and rigorous. The New Jersey Department of Environmental Protection has been progressive in efforts to protect public health from PFOS, PFOA, and other perfluorochemical exposures. We concur with the process used to derive a PFOS reference dose, concluding with the Dong et al (2009) study showing an immunotoxic effect in test animals.

However, all population segments must be protected. Our analysis finds that at the proposed 13 ng/l MCL, PFOS daily intakes by body weight posed to young children 1-6 would be more than double the PFOS dose of 1.8 ng/kg/day deemed allowable by NJDWQI. This is disconcerting since existing serum PFOS levels in children in the population are already within or near serum PFOS levels associated with immunotoxic effects found in epidemiologic studies. The developing fetus, infants, and young children are particularly sensitive to PFOS and PFOA exposures during early sensitive periods. Early PFOS exposures in children, even at low doses of 1.8 ng/kg/day, may affect risk for later disease manifestation. To assure protection of children's health NJDWQI should depart from using adult default exposure values and use children-specific exposure values in its MCL derivation, as described in this review.

We recommend an MCL of 5 ng/L, as calculated above based on children exposure values.

Alternatively, due to PFOS and PFOA co-occurrence in water supplies and additivity concerns, we recommend that the combination of PFOS and PFOA concentrations in water supplies be no higher than 13 ng/L. $[PFOA + PFOS] \le 13$ ng/L

exposure. In addition, perfluorinated compounds do not cross the dermal barrier. However, further testing is needed to assure that POU GAC/RO systems remove PFOS, PFOA, and PFNA to low ppt levels. Use of POU GAC/RO systems is somewhat complicated by the requirement of homeowner management of carbon change-out and proper operation.

Conclusion

The proposed New Jersey MCL of 13 ng/L, our recommended MCL in this review of 5 ng/L, the Minnesota limit (HRL) of 27 ng/L, and the Vermont drinking water advisory of 20 ng/L (combined) for PFOS are within the same very small "ballpark". Changing an uncertainty factor or exposure value used in these derivations obscures the difference in values. Accordingly, further emphasis should be placed on treatment and removal.

In addition to shorter chain perfluorinated compounds such as PFBS and PFBA, PFOA usually coexists with PFOS in water supplies. Although the shorter chain perfluorinated compounds (e.g. PFBA, PFBS) are less toxic and excreted faster than longer chain perfluorinated compounds (e.g. PFOS, PFOA), they remain persistent, as demonstrated in the Oakdale, MN drinking water supply. The toxicity of shorter chain perfluorinated compounds is not fully understood, although toxicity of PFBA has been shown in animal testing and, in the case of Minnesota, a health risk limit (limitation) has been derived. There are differential removal efficiencies among perfluorinated compounds in GAC systems. PFOA is often poorly removed by GAC alone, as described in the full-scale GAC operating systems and research discussed above. Short chain perfluorinated carboxylic acids (e.g. PFBA) generally remain unchanged (not removed) through GAC systems.

The treatment system chosen for removal of perfluorinated compounds must be capable of removing both PFOA and PFOS, as well as providing best treatment technology available to remove other perfluorinated compounds, such as PFBA, that pose some toxicity. Removal of shorter chain perfluorinated compounds requires reverse osmosis in addition to GAC. Granular activated carbon (GAC) followed by reverse osmosis, or nanofiltration if pilot-scale studies demonstrate efficiency, is needed as a combined option to adequately remove both PFOS and PFOA, as well as other perfluorinated compounds that may be present.

Re: Comment on the DWQI Draft Second Addendum to Appendix C: Recommendation on Perfluorinated Compound Treatment Options for Drinking Water (PFOS), November 2017

Please find enclosed a technical analysis prepared by Don Kriens, Sc.D., P.E. of Cambridge Environmental Consulting commissioned by Delaware Riverkeeper Network and submitted on behalf of this organization and its membership on the Drinking Water Quality Institute's document **Draft Second Addendum to Appendix C: Recommendation on Perfluorinated Compound Treatment Options for Drinking Water (PFOS), November 2017.**

Also enclosed is a copy of the Curriculum Vitae for Don Kriens, Sc.D., P.E.

Delaware Riverkeeper Network submits these comments advocating that the public be protected from PFOS contamination and that New Jersey's drinking water be required to be treated to a safe level based on the best available scientific evidence and the most effective treatment technologies.

We support the recommendations and findings made by Don Kriens of Cambridge Environmental Consulting in this technical analysis regarding the Draft Second Addendum to the Treatment Options Report by the DWQI. We support the utilization of the most effective methods of removing perfluorinated compounds (PFCs), including PFOS, considering the highly toxic properties of these compounds.

Cambridge Environmental Consulting recommends granular activated carbon (GAC) combined with reverse osmosis technology (RO) to completely remove all PFCs from drinking water to the proposed safe drinking water standards. Dr. Oliaei and Don Kriens recommend further research on nanofiltration, which may demonstrate adequacy to remove PFOA, PFOS and lower carbon number PFCs as a substitute for RO. Delaware Riverkeeper Network supports these findings and advocates for the use of the best available technology that will be capable of removing both PFOS and PFOA as well as other PFCs such as shorter chain PFCs with a goal of providing safe drinking water to the public.

DELAWARE RIVERKEEPER NETWORK 925 Canal Street, Suite 3701 Bristol, PA 19007 Office: (215) 369-1188 fax: (215)369-1181 drn@delawareriverkeeper.org www.delawareriverkeeper.org Thank you for the opportunity to comment on the Treatment Options to remove PFCs, including PFOS.

Sincerely,

Wato K. row boun

Review of New Jersey Second Addendum to Appendix C: Recommendation on Perfluorinated Compound Treatment Options

prepared by

Don L. Kriens Sc.D., P.E.

Cambridge Environmental Consulting

January 2018

Executive Summary

The treatment system must be capable of removing both PFOA and PFOS, as well as providing best treatment technology available to remove other perfluorinated compounds, such as PFBA, that pose some toxicity. GAC alone does not remove low carbon number perfluorinated carboxylic acids (e.g. PFBA) and, at times, low carbon number perfluorinated sulfonic acids (e.g. PFBS). There are differential removal efficiencies among perfluorinated compounds through GAC systems. As described in the full-scale GAC operating systems and research discussed herein, PFOA is often marginally removed by GAC alone. Granular activated carbon (GAC) followed by reverse osmosis technology is needed at public water treatment systems to assure removal of all perfluorinated compounds. Further testing of nanofiltration, as discussed in the Subcommittee's Recommendation on Perfluorinated Compound Treatment Options (2015), may demonstrate adequacy to remove PFOA and low carbon number perfluorinated compounds, as a substitute for reverse osmosis.

Prevalence of PFCs in New Jersey Drinking Water

PFOS and PFOA are found in New Jersey water supplies at relatively high concentrations, in some instances at levels greater than the existing 14 ng/l MCL for PFOA and the proposed 13 ng/l MCL for PFOS. We expect that in excess of one million people are ingesting PFOS and PFOA at these levels. PFOS levels in some New Jersey PWS (public water supplies) are such that ingestion of this contaminated water further increases residents' PFOS blood serum levels beyond those already found in epidemiologic studies in the U.S. population to be associated with adverse health effects (immunotoxicity).

Following discovery of PFOA levels in PWS (public water systems) at levels up to 190 ng/l in groundwater and 64 ng/l in tap or finished drinking water, New Jersey Department of Environmental Protection completed two studies, in 2006 and 2009-2010, to test for PFOS, PFOA, and other perfluorinated compounds in 53 PWS (NJDWQI 2017).

PFOS was found in the 2006 study in 30% of 23 PWS tested at or above the minimum reporting limit (MRL) of 4 ng/L (NJDWQI 2017), with the highest PFOS level at 19 ng/L (NJDWQI 2017). In the 2009-2010 study raw water was tested in 30 PWS in 19 of New Jersey's 21 counties. PFOS was found in 8 of 29 PWS sampled at levels up to 12 ng/L in 5 PWS using groundwater, and up

to 43 ng/L in 3 PWS using surface water (NJDWQI 2017). Finished drinking water in these PWS would be expected to contain the same concentrations, since minimal to no removals of perfluorinated compounds are achieved through conventional water treatment technologies.

Testing of 175 New Jersey PWS, including 165 large community systems and 10 small community systems, completed under the UCMR3 (Third Unregulated Contaminant Monitoring Rule) found 6 PWS with PFOS levels exceeding 40 ng/L, and 18 PWS with PFOA levels exceeding 20 ng/L (UCMR3 2017, NJDWQI 2017). Based on the New Jersey DEP database we note that 10 of 76 PWS tested were found to contain PFOS ≥ 20 ng/l, with 7 PWS containing PFOS at levels exceeding 40 ng/L.

The 80 PWS tested represent about 14% of the total community water supplies in New Jersey. In 2016 New Jersey had 581 community water systems (NJ DEP Division of Water Supply and Geoscience 2017), serving about 91% of the total population, of which 42% were medium to large systems, and 58% were small systems.

State-wide studies of PFOA and PFOS in private wells have not been conducted in New Jersey. About 12% of New Jersey's population obtains drinking water from private wells (NJDEP Division of Water Supply and Geoscience 2017). Although it is likely the majority of these wells are not contaminated, groundwater at locations proximate to industrial activities using perfluorinated compounds or where AFFF (aqueous fire fighting foam) has been used may exhibit levels of PFOS and PFOA. PFOA has been found at levels exceeding 40 ng/L (maximum >400 ng/L), in 59 private wells within 2 miles of a New Jersey industrial source (NJDWQI 2016 Report, DuPont, 2009). PFOS was found in private wells at levels above the USEPA advisory of 70 ng/L (PFOS + PFOA) and the proposed MCL of 13 ng/L near sites contaminated with fire fighting foam (NJDWQI 2017).

Treatment Technologies and Capabilities, Chemistry of PFSAs versus PFCAs

The NJDWQI Treatment Subcommittee states in its 2015 report, Appendix C: Recommendation on Perfluorinated Compound Treatment Options for Drinking Water: "the treatment options are not expected to differ from compound to compound due to their similar properties (e.g. persistence, water solubility, similar structure, strong carbon-fluorine bonds, and high polarity)". The NJDWQI subcommittee does not diverge from this position in the Appendices to the 2015 Report. We disagree with this position. Peer-reviewed studies show that treatment options differ in removal capability among perfluorinated compounds.

Although perfluorinated compounds have somewhat similar structure, polarity, and solubility, there are differences in structural chemistry that affect removal among treatment options. Specifically, the charged functional group, carboxylic or sulfonic acid, affects the adsorption capability of activated carbon. PFSAs (perfluoroalkyl sulfonic acids, e.g. PFOS) are stronger acids and more hydrophobic compared to PFCAs (perfluoroalkyl carboxylic acids, e.g. PFOA, PFBA). Therefore, their tendency to adsorb onto activated carbon is greater.

In a review of adsorption behavior of perfluorinated compounds (mostly PFOS and PFOA) by Du

et al. (2014) sorption capacities of PFSAs (e.g. PFOS) onto activated carbon or other adsorbents were observed to be higher than PFCAs (PFOA) with the same carbon numbers due to greater hydrophobicity of PFSAs versus PFCAs (Du et al. 2014).

Activated column experiments by Ostlund (2015) found higher removal efficiency of PFSAs than PFCAs, comparing the same number of carbons in the perfluorocarbon chain length, indicating that that functional group affects removal efficiencies of PFASs; "sulfonic group resulted in higher removal efficiency compared to carboxylic group" (Ostlund 2015). This study also found that branched isomers (for PFOS) were less efficiently removed by GAC (granular activated carbon) compared to linear PFOS isomers. We note this finding could, in part, account for differences in PFOS removal among locations using GAC.

The Water Research Foundation study of 15 full-scale water treatment systems in the U.S., including two potable reuse treatment systems, found that full-scale anion exchange and GAC column treatments were more effective at removing long-chain perfluorinated compounds and PFSAs (e.g. PFOS) versus PFCAs (e.g PFOA, PFBA) (Water Research Foundation 2016). Full-scale reverse osmosis systems demonstrated significant removal for all perfluorinated compounds, including the smallest, perfluorobutanoic acid (PFBA).

The WRF (2016) study further evaluated nanofiltration (NF) for removal of a suite of PFCAs and PFSAs and notes that NF "has been deemed potentially effective (> 95%) in bench-scale experiments using NF270 membranes" (WRF 2016; Steinle-Darling and Reinhard 2008). WRF (2016) indicated that NF may be as capable of rejecting (treating) perfluorinated compounds as reverse osmosis at lower cost.

A study of sorption onto GAC, zeolite, and sludge found that PFOS is strongly adsorbed by GAC; PFOA and PFBS were also removed by GAC but to a lesser extent. The authors noted "that the length of the fluorocarbon chain and the nature of the functional group influenced sorption of the anionic surfactants" (Ochoa-Herrera and Reyes-Sierra 2008).

Perfluorinated compound removal was studied at two water reclamation plants (treating domestic effluents as influent) in Southeast Queensland, Australia. In the treatment plant using reverse osmosis, PFOA was removed to less than reporting level to 1.4 ng/L, from influent levels ranging from 15 to 27 ng/L, and PFOS was removed to less than reporting with influent PFOS levels ranging from 23 to 39 ng/L. In the treatment plant using biologically activated carbon, PFOA and PFOS were ineffectively removed, although lack of removal may have been due to the age of the carbon or short contact times (Thompson et al., 2011).

In a study at a water treatment plant in Amsterdam using GAC, PFOA was not effectively removed, with a final (treated) mean PFOA concentration of 5.3 ng/L (range 0.8 ng/L - 9.4 ng/L) versus a mean influent (raw) PFOA concentration of 4.4 ng/L (range 3.8 ng/L - 5.2 ng/L). The authors found greater removals of PFOS and PFNA with a mean final (treated) water level of <0.23 ng/L and <0.24 ng/L, respectively, versus influent (raw) levels of 6.7 to 10 ng/L for PFOS and 0.5 to 0.8 ng/L for PFNA (Eschauzier et al. 2012). This study also found that PFBA, PFPeA,

PFHxA, PFOA, and PFBS were not well removed by the (operating) GAC filtration. In general, the authors found that PFOA decreased by only 50% using GAC.

A study in Spain suggests that although GAC alone was reasonably effective to remove PFOS, reverse osmosis was needed to achieve efficient PFOA removal. In this study 2 separate stages following conventional water treatment (GAC, or Ultrafiltration followed by Reverse Osmosis) were evaluated. The system treats 100 million gallons per day of surface river water to supply over 1 million inhabitants. The authors found that ultrafiltration/reverse osmosis removed PFOS and PFOA by \geq 99%, but GAC alone removed PFOS and PFOA by only 64 \pm 11% and 45 \pm 19%, respectively (Flores et al. 2013).

In a study monitoring drinking water treatment facilities across the U.S., a utility that used microfiltration and reverse osmosis for indirect potable reuse in wastewater treatment reduced total perfluorinated compound influent levels of 80 ng/L and influent PFOS of 41 ± 18 ng/L to no reportable levels. Minimum reporting levels were 1.0 ng/L for all perfluorinated compounds monitored except PFOA, where the minimum reporting level was 5 ng/L (Quinones and Snyder 2009).

Granular Activated Carbon Treatment Systems - Removal Efficiency

NJDWQI subcommittee describes 2 facilities in New Jersey, one in Pennsylvania, and one in Minnesota where GAC is used to treat perfluorinated compounds in public water supplies.

In the New Jersey Penns Grove GAC treatment system PFOS was reported at levels lower than the reporting limit of 5 ng/l in finished water, although the highest PFOS level in the raw water was 13 ng/L. At the New Jersey Logan System Birch Creek GAC system PFOS was reported at levels lower than the reporting limit of 5 ng/l in finished water, although the average PFOS raw water concentration was only slightly above the reporting limit, at 7 ng/L. We believe that PFOS and PFOA removal performance may be much different at other locations, where PFOS and PFOA are present in raw water at higher levels and/or where source water contains greater natural organic matter.

The Subcommittee notes the Horsham Water and Sewer Authority (HWSA) in Horsham, Pennsylvania, where GAC was recently installed to treat well water contaminated with perfluorinated compounds. Wells are believed contaminated from fire fighting foam used at the nearby Naval Air Station Joint Reserve Base - Willow Grove. NJDWQI subcommittee states that HSWA raw (well) water samples collected between January and March 2017 "show a range of PFOS concentrations from 230 - 1297 ng/L and an average of 629.3 ng/L", and indicates PFOS was not detected in finished water. We characterize HSWA well data differently, based on our review of HWSA active well data (HWSA, PFOS PFOA Active Source Monitoring Results with Charts, 2017), as summarized in Table 1 below.

We observed that, during limited periods, post-GAC treatment in 4 HSWA contaminated wells

did not remove PFOS or PFOA to levels below the reporting limit of 5 ng/L. This appeared to occur just prior to carbon change-out, as shown in the HSWA data. However, it should be noted that GAC treated water is also blended with other HSWA wells and water sources, as shown in HSWA system schematics (HSWA June 2016), to assure that levels are below applicable standards and protective. As of December 2017 the HSWA indicates "the combined concentration of PFOS/PFOA from all sources currently supplying the public system is approximately 4 ppt (ng/l)" (HSWA Dec 2017 Update). This is below the USEPA health advisory level applied of 70 ppt (ng/l) for combined concentration (PFOA + PFOS).

Based on HSWA data as of December 19, 2017, the following table summarizes results for active HSWA wells (HWSA, PFOS PFOA Active Source Monitoring Results with Charts, 2017).

HSWA well number	Period	PFOS lowest	PFOS highest	PFOA lowest	PFOA highest
7	May 5, 2016 - Dec 19, 2017	- ND	11	3.1	. 11
10*	Jan 19, 2016 - April 5, 2017	16	76	12	48
17**	Jan 19, 2016 - Dec 22, 2016	50	110	20	37
21***	Jan 2016 - Jan 11, 2017	5.1	14	8.4	13
26****	Jan 25, 2016 - March 8, 2017	340	1297	640	1765
40****	Jan 11, 2017 - March 24, 2017	230	1203	33	88

Table 1. Summary Table of HSWA Raw Water PFOS and PFOA Concentrations (ng/L)

ND – non detect at reporting limit 5 ng/L

^{*}After April 5, well 10 was treated through GAC system with N.D results.

^{**} After December 22, 2016 well 17 was treated with GAC. Results post GAC treatment in 2017 mostly ND (reporting levels 5 ng/L), except for 6 positive PFOS values ranging from 3.1 to 159 ng/L, and 5 positive PFOA values ranging from 13 ng/L to 29 ng/L.

^{***} After January 2017 well 21 was treated with GAC. Results post GAC treatment ND (reporting levels 5 ng/L), except one PFOS value of 4.2 ng/L, and 5 PFOA values ranging from 3.3 to 7.8 ng/L.

^{****} After March 8, 2017 well #26 was treated with GAC. Results post GAC treatment ND, except for one PFOS value of 5 ng/l and one value of 5 ng/L for PFOA

^{*****} After March 24, 2017 well #40 treated with GAC. Results post GAC treatment ND, except 4 PFOS

values ranging from 2.5 $\,$ ng/L - 131 $\,$ ng/L and 3 PFOA values ranging from 3.1 $\,$ ng/L to 5.3 $\,$ ng/L

The Second Addendum discusses the city of Oakdale, Minnesota GAC system used to remove perfluorinated compounds, including PFOS, from well (drinking) water. NJDWQI subcommittee notes that the Oakdale PFOS method detection limit is 0.5 ng/L and the Minimum Reporting Limit (MRL) is 5 ng/L. However, these limits were only recently put into effect by the Minnesota Department of Health (Rinker communication, Jan 5, 2018). (A MRL for PFOA of 5 ng/L was also recently put into effect.) Prior RLs (reporting limits) for PFOS and PFOA at Oakdale were 25 ng/L and 35 ng/L, respectively. The Subcommittee states that "samples taken after GAC treatment show no detection of PFOS". However, these non-detects are based on the prior RLs (25 ng/L and 35 ng/L), not 5 ng/L. It is yet unknown whether the Oakdale GAC system will remove PFOS or PFOA to ≤ 5 ng/L.

Based on Oakdale's perfluorinated compound data (Bachmeier 2017), PFOS was non-detect in finished drinking water for the period November 2015 through November 2017, at a RL of 50 ng/L for the period November 2015 through July 2016, and a RL of 25 ng/L for the period August 2016 to present. PFOA was non-detect for all samples at a RL of 50 ng/L for the period November 2015 through July 2016, and a RL of 35 ng/L for the period August 2016 to present. We observed that PFBA (perfluorobutanoic acid) remains at relatively high levels in Oakdale's drinking water, typically at around 1400 ng/L, consistent with other installations and research showing poor or no removal by GAC of low carbon number PFCAs. Generally PFBA passes through unchanged in concentration through the Oakdale GAC system. However, PFBA levels in Oakdale's finished water are well below the Minnesota Department of Health HRL (health risk limit) for PFBA of 7000 ng/L.

The 3M Cottage Grove manufacturing plant in Cottage Grove, Minnesota operates a GAC system to treat wastewater discharged to the Mississippi River, installed in 2004 pursuant to requirement by the NPDES (National Pollutant Discharge Elimination System) permit. 3M was the primary global producer of PFOS-related perfluorinated compounds, and PFOA, and manufactured these chemicals at its two U.S. plants in Decatur, Alabama and Cottage Grove, Minnesota, and in Europe at its plant in Antwerp, Belgium. 3M perfluorochemical production began at the Minnesota plant around 1950 (Oliaei et al. 2006).

Based on one sampling event in 2006 by Minnesota Pollution Control Agency staff, the 3M GAC treatment facility removed PFOS by 95% and PFOA by 79%. The GAC treatment plant was less effective at removal of carboxylic perfluorinated compounds (PFCAs). In the 2006 sampling of post-GAC treated wastewater perfluorinated compound concentrations were very high: PFOA 1670 ng/L, PFOS 1330 ng/L, PFBS 169,000 ng/L, and PFBA 58,100 ng/L (Oliaei et al. 2006).

Since 2006 levels of perfluorinated compounds in the 3M discharge (post-GAC treated wastewater) are considerably lower, but remain elevated, as summarized in the following table for the period October 2015 through November 2017 (NPDES 3M data provided by Marco Graziani, Minnesota Pollution Control Agency, January 2018).

~ mean	172	36555	<25	43	2031

Table 2. 3M Perfluorinated Compound Discharge (SD001) Post-GAC Treatment ng/L

Mean concentrations in Table 2 are means of positive values, excluding non-detects. The post-GAC discharge perfluorinated compound discharge concentrations for October 2015 to present remain high: mean PFOA 172 ng/L, mean PFBA 36,555 ng/L, mean PFOS 43 ng/L, and mean PFBS 2031 ng/L. However, these concentrations are much lower than those discharged during the period January 2007 though July 2010: mean PFOA 2989 ng/L, mean PFBA 54,098 ng/L, mean PFOS 595 ng/L, and mean PFBS 18,673 ng/L. The 3M data indicate that low carbon perfluoroalkyl compounds (such as PFBS and PFBA) and PFCAs (e.g. PFBA, PFOA) are not removed by this GAC system to low levels.

Recommended Treatment - GAC Followed by Reverse Osmosis

GAC alone has not been shown in most cases to consistently remove PFOA to low ng/L levels. Therefore, GAC followed by reverse osmosis (RO) is required to remove PFOA and, in some cases PFOS, to assure consistent removal. GAC followed by RO will also enable removal of low carbon number perfluorinated compounds such PFBA. PFBA has been shown in animal studies to cause toxicity. The Minnesota Department of Health identified critical toxic effects of "liver weight changes, morphological changes in liver and thyroid gland, decreased TT4, decreased red blood cells, decreased hematocrit and hemoglobin, and subcritical toxic effects of increased relative thyroid weight, decreased serum TT4 and dFT4, decreased cholesterol, and delayed eye opening (rat)", in PFBA animal studies as the basis to derive a HRL (health risk limit) for PFBA (MDH 2017 Perfluorobutyrate).

A consideration using GAC/RO in large municipal treatment systems is disposal of the RO reject. Technologies to treat RO reject are generally limited to evaporative technologies applied to high salt concentrating RO systems, to eliminate the reject discharge. Evaporative systems require excessive energy input and are often prohibitively expensive. RO reject evaporative systems may be relatively cost effective, however, in arid climate locations to allow lined evaporation ponds, or where untreated reject water does not pose a concern or environmental impact (such as RO systems used for drinking water treatment in coastal areas, where the salt RO reject is discharged to the ocean). Such is not the case for the temperate geographic region under consideration in New Jersey. Thus, RO rejects at large GAC/RO plants would likely require direct discharge to a receiving water.

The GAC system, however, will enable removal of a significant mass of PFOS, and to a lesser extent, PFOA. A primary concern with waters receiving perfluorinated compounds is uptake of PFOS in fish, which bioaccumulates, and subsequent consumption of PFOS-contaminated recreationally caught fish. PFOA does not bioaccumulate. In any case, the mass of perfluorinated compounds, including PFOS and PFOA, discharged to a receiving water in a GAC followed by reverse osmosis system (reject) would not be greater than the mass discharged by a GAC system alone.

NJDWQI briefly discusses Point of Use (POU) drinking water systems, for use in individual homeowners on private wells, and certification by NSF (National Sanitation Foundation). NSF developed protocol NSF P473 to evaluate drinking water treatment device capability to reduce PFOA and PFOS in drinking water. The NSF certified a number of systems using GAC or GAC/RO that meet the EPA "standard" (combined PFOS and PFOA) of 70 ng/L. The NSF protocol included "challenge" of influent level of 1500 ng/L [5 parts PFOA and 10 parts PFOS by weight] to the GAC and GAC/RO systems. Studies by NSF showed good removal performance by GAC with highest performance in POU systems using GAC followed by reverse osmosis (NSF personal communication, E. Valentine, Jan 4, 2018)

We concur that GAC/RO POU systems offer a treatment solution to homeowners on private wells. Perfluorinated compounds do not volatize and therefore inhalation via showering and bathing do not pose an exposure pathway, versus other compounds such as DBPs (disinfection byproducts) where inhalation in showering may comprise a significant portion of total

Re: Report on the Development of a Practical Quantitation Level for Perfluorooctanesulfonic Acid (PFOS) in Drinking Water, NJ Drinking Water Quality Institute Testing Subcommittee

Please find enclosed a technical analysis prepared by Fardin Oliaei, MPA, PhD, and Don Kriens, Sc.D., P.E. of Cambridge Environmental Consulting commissioned by Delaware Riverkeeper Network and submitted on behalf of this organization and its membership on the Drinking Water Quality Institute's document Report on the Development of a Practical Quantitation Level for Perfluorooctanesulfonic Acid (PFOS) in Drinking Water.

Also attached are copies of the Curriculum Vitae for Dr. Oliaei and for Don Kriens, Sc.D., P.E.

Delaware Riverkeeper Network submits these comments advocating that the public be protected from PFOS contamination and that New Jersey's drinking water be required to be treated to a safe level based on the best available scientific evidence.

We support the recommendations and findings made by Dr. Oliaei and Cambridge Environmental Consulting in this technical analysis regarding a Practical Quantitation Level (PQL) for PFOA. We support Cambridge Environmental Consulting's concurrence with the DWQI Testing Subcommittee's analysis that determined a PQL on the basis of multiplication of the method detection limit by a factor of 5, resulting in a PQL of 4.2 ng/L for PFOS. The PQL of 4.2 ng/L is below the MCL of 5 ng/L that Cambridge Environmental Consultants recommends as more protective. Thank you for the opportunity to comment on the PQL for PFOS.

Sincerely,

Maya van Rossum

the Delaware Riverkeeper

Tracy Carluccio Deputy Director

Review of NJDWQI Report on the Development of a Practical Quantitation Level for PFOS in Drinking Water

prepared by
Fardin Oliaei Ph.D. and Don L. Kriens Sc.D.
Cambridge Environmental Consulting
January 2018

The NJDWQI Testing Subcommittee determined that use of low calibration standards for PFOS among laboratories was the most appropriate performance standard to base a practical quantitation limit (PQL). Using low calibration standards of 19 laboratories that used either EPA Method 537, modified EPA Method 537, or a proprietary method, the Subcommittee applied bootstrap analysis (bootstrap estimate of a confidence interval of the mean) to determine an upper confidence limit of 95% for PFOS at 4.2 ng/L. (One laboratory with a low calibration standard above the upper confidence level (95%) was excluded.) The same methodology was applied to 12 laboratories using EPA Method 537 to determine an upper confidence limit (95%) of 3.8 ng/l. (Two laboratories were excluded from that analysis since their low calibration standards were outside the 95% confidence interval.)

The Subcommittee's methodology appropriately diverts from the prior or traditional use of developing a PQL on the basis of multiplication of the MDL (method detection limit) by a factor of 5, consistent with USEPA "trend" not to use MDLs to develop a PQL.

We concur with the Subcommittee's analysis that determined a PQL of 4.2 ng/l for PFOS. This PQL concentration is below the proposed MCL of 13 ng/l, and below the 5 ng/l that we assert is more protective.

PROFILE

- Accomplished scientist with years of experience in creating innovative solutions to challenging environmental problems related to public health, policy development and environmental sustainability.
- Experienced project manager with skills in the application of analytical methods and techniques necessary for working within the framework of state/federal environmental and public health organizations.
- Registered independent consultant in the UNEP and UNIDO experts' roster for U-POPs and New-POPs and implementation of the Stockholm Convention on Persistent Organic Pollutants.
- Rigorous researcher and team leader experienced in spearheading all phases of (planning, budgeting, developing, conducting, and directing) of environmental project management.
- Effective communicator with ability to translate complex scientific data into coherent material in order to inform audiences with varying degrees of knowledge about environmental issues.
- Conscientious professional with experience presenting expert witness testimony in litigation cases involving a wide range of environmental problems and related public health issues.
- Experienced college instructor developing and teaching natural sciences and environmental science and public health policy courses.

EDUCATION

Harvard University School of Public Health, Boston, MA

Auditing several courses: Air Pollution; Water Pollution; and Risk Assessment

2010 - 2012

Harvard University John F. Kennedy School of Government, Cambridge, MA

Master in Public Administration

2009

• Concentration: Leadership and International Environmental Health Policy and Management

Bush Foundation Leadership Fellow (MN) to pursue studies at Harvard University 2008 - 2010

Western Michigan University, Kalamazoo, MI

PhD in Environmental Sciences

- Dissertation title: Acid Rain and Lake Acidification Impacts on Aquatic Life
 MS in Biology
- Thesis title: Drinking Water Quality and Waterborne Diseases in Rural Iran

National University of Iran, Tehran, Iran BS in Chemistry Minor in Biology

PROFESSIONAL EXPERIENCE

DST Health Solutions, LLC, Home Office East

2014 - Present

Sr. Project Management Specialist

Evaluating the global pattern of disease and morbidity in growing population and identifying social determinants of population health as a tool for managing healthier population and creating effective health care systems.

Cambridge Environmental Consulting, LLC, Boston, MA Senior Scientist and President

- "Visiting Professor" at the Iranian National Institute of Oceanography (INIO) conducted training workshops for INIO staff/scientist and coastal management professionals on the policy aspects of coastal zone management and its implications. The training was tailored to the local cultural characteristics, government structure, resource integrity, and management needs of the country (2012).
- Invited by the Iranian Governor's Officials to visit and evaluate the environmental impacts of a historically contaminated site caused by the largest landfill located near the Caspian Sea. Developed an integrated solid waste management plan for implementation, including an assessment of all environmental risks, and the development of mitigation efforts required to minimize the adverse impacts on Public health and the environment (2012).
- Participated and presented two papers at Dioxin 2010 30th International Symposium on Halogenated Persistent Organic Pollutants (POPs) on 1) Presence of PBDEs in Minnesota Landfills Environmental Releases and Exposure Potential, and 2) Investigation of PFOS/PFCs Contamination from a PFC Manufacturing Facility in Minnesota Environmental Releases and Exposure Risks (2010).
- Chaired the "New POPs" Section (Implication of Stockholm Convention of New POPs) of the 11th International HCH and Pesticide Forum, Cabala, Azerbaijan (2012).
- Serve as expert witness in environmental litigation pertaining to release of industrial toxic contaminants.
- Conduct evaluations of toxic contaminants (including New POPs) and use dispersion modeling (groundwater, surface water, soils and air) to evaluate contaminants' environmental impacts and public health risks.
- Review and evaluate EPA documents related to the issuance of new source National Pollutant Discharge Elimination System (NPDES) permits to industrial activities.

Women's Environmental Institute (WEI), St. Paul, MN Principal Scientific Consultant

2006 - 2012

- Served as a WEI Board Member and later, as the principal scientific consultant, developed environmental justice education program to promote environmental awareness, sustainability, and health disparity.
- Directed and managed projects on environmental issues related to public health and environmental quality.
- Analyzed the effectiveness and efficiency of existing environmental and public health programs for the implementation and administration of programs best fit the affected communities. Identified and presented to public policy makers the problems affecting concerned communities.
- Evaluated the impact of toxic pollutants on the growth and development of exposed children. Developed multimedia outreach programs to inform families about toxic exposure and consequences.
- Developed culturally specific environmental training and educational seminars for exposed communities through different radio stations and newspapers.

Mote Marine Laboratory, Sarasota, FL Associate Scientist

2007-2008

- Designed health risk assessment framework to evaluate potential exposure pathways and toxicity effects of contaminants in Florida manatees. Contributed to development of research proposals.
- Evaluated public and environmental regulatory policies and proposed effective mitigation tools

Minnesota Pollution Control Agency (MPCA), St. Paul, MN

1989 - 2006

Senior Scientist, Project Manager, and Emerging Contaminants Program Coordinator

- Developed policy, program analysis methods, and multimedia strategy to assess health impact of toxic chemicals.
- Initiated and led the Emerging Contaminants Program for the competent authority (MPCA).
- Prepared Environmental Impact Assessments (EIS) for major projects in MN and communicated the results, including the potential social, and economic impacts of these projects with authorities and public.
- Represented the MPCA as a scientific expert, liaison, and critical state contact in the PCBs, Dioxin, and emerging contaminants activities of the US EPA, Great Lakes Binational Strategy (GLBNS) and in other related national and international programs.
- Worked closely with diverse array of clientele and stakeholders (federal and state governments, industry, grass root organizations, affected communities, and the state legislators) to develop progressive environmental policies and educational materials.
- Presented at international conferences and gave presentations regarding environmental issues in public meetings, legislative hearings and governmental agencies.
- Managed contracts and secured federal/state grants and awards for health impacts of contaminant in Minnesota.
- Developed statewide air toxics monitoring/bio-monitoring network using mass balance and integrated air exposure-effect models.
- As the technical coordinator and MPCA liaison, built partnership between PCA and other sister agencies (MN Department of Health, MN Department of Natural Resources, and MN Department of Agriculture), USA EPA, and MN university researchers for ongoing efforts to identify, evaluate, control, regulate, and reduce the emerging pollutants with endocrine disruptive characteristics (PFOS and PFOA, PBDEs, and pharmaceuticals).
- Assessed the current regulations and programs already in place that may be addressing reduction of toxic contaminants of concern, identified unregulated emerging contaminants of greatest potential risk to human health and the MN environment, rationale of why these contaminants need to be regulated.

TEACHING EXPERIENCE

Teach biology, chemistry, environmental science, health and policy-related courses (Elements of Health and Wellness, Foundations of Research, Public Policy Planning and Implementation), part-time at:

Re: Report on the Proposed DWQI Development of a Practical Quantitation Level for Perfluorooctanoic Acid (PFOA) in Drinking Water

Please find enclosed a technical analysis prepared by Fardin Oliaei, MPA, PhD, and Don Kriens, Sc.D., P.E. of Cambridge Environmental Consulting commissioned by Delaware Riverkeeper Network and submitted on behalf of the organization and its membership on the Drinking Water Quality Institute's document **Development of a Practical Quantitation Level for Perfluorooctanoic Acid (PFOA).**

Also attached is a PDF containing the Curriculum Vitae for Dr. Oliaei and for Don Kriens, Sc.D., P.E.

Delaware Riverkeeper Network submits these comments advocating that the public be protected from PFOA contamination and that New Jersey's drinking water be required to be treated to a safe level based on the best available scientific evidence.

We support the recommendations and findings made by Dr. Oliaei and Cambridge Environmental Consulting in this technical analysis regarding a Practical Quantitation Level (PQL) for PFOA. We support the utilization of the most accurate measurements of PFOA in water that can be achieved at the lowest reporting limits. Since the MCL recommended by Dr. Oliaei and Don Kriens is 1 ng/L, Delaware Riverkeeper Network supports using the most sensitive measurement method.

There are two methods recommended as alternatives to the EPA technique "Bootstrap Estimate of a Confidence Interval of a Mean". Using the method detection limit (MDL) approach, Dr. Oliaei's and Don Krien's calculations yielded a PQL of 3.0 ng/L. To use the minimum reporting level (MRL) approach to determine a PQL for PFOA, Dr. Oliaei and Don Kriens propose a MRL of 2 ng/L.

Thank you for the opportunity to comment on the PQL for PFOA.

DELAWARE RIVERKEEPER NETWORK 925 Canal Street, Suite 3701 Bristol, PA 19007 Office: (215) 369-1188 fax: (215)369-1181 drn@delawareriverkeeper.org www.delawareriverkeeper.org Sincerely,

PREFACE

The opinions in this report are stated to a reasonable degree of scientific probability. The methods and principals used in forming these opinions are generally accepted within the scientific community and are consistent with their regular application within the scientific community. Qualifications of the authors, including publications where applicable, are summarized in the attached resumes. We reserve the right to modify or supplement opinions stated in this report.

^{*} The views expressed in this report do not necessarily reflect those of the Harvard T.H. Chan School of Public Health, Harvard University, of which the author is affiliated as a Research Fellow.

Technical Analysis of Proposed NJDWQI Development of a Practical Quantitation Level for Perfluorooctanoic Acid

by

Cambridge Environmental Consulting

Introduction

Different laboratories, programs and methods have different terminology for similar concepts. In general, the Method Detection Limit (MDL) and derivative Practical Quantitative Level (PQL) are used to estimate the limits of performance of analytical methods for measuring contaminants. The MDL is the minimum detection capability of a particular method reported by each laboratory and defined as the concentration of a contaminant (with true value greater than zero) that can be measured and reported with 99% confidence. The PQL is the lowest concentration for which the contaminant can be reliably quantified within specified limits of precision, accuracy and acceptable limits of uncertainty. There are also method specific Minimum Reporting Levels (MRL) which are similar in concept to a PQL. Analytical methods are changing and improving over time, thus, lowering the values of MDL, MRL, and PQL.

To develop an appropriate PQL requires evaluation of analytical methods with adequate sensitivity to detect PFOA at or below a proposed health based Maximum Contaminant Level (MCL).

The PQL for PFOA has been determined as a result of performance data compiled from three selected data sources by the testing committee. The Testing Subcommittee considered the RLs, lowest calibration standards and MDLs from laboratories that meet at least one of the criteria below:

- 1. The laboratories that analyzed water samples for PFOA during the NJDEP 2006 and 2009 studies;
- 2. The laboratories must use PFOA methods that have been vetted by the NJDEP OQA, NELAP or EPA; and
- 3. The laboratories must be EPA UCMR3 approved and demonstrated capability of reporting PFOA lower than the UCMR3 MRL of 20 mg/L using EPA 537 or modifications of EPA 537.

The Testing Subcommittee evaluated the following three methods for deriving the PQL for PFOA:

A. Determination of the PQL using MDLs

According to Testing Subcommittee report, the determination of the PQL using MDLs requires a sample size of at least five MDLs from which to obtain an inter-laboratory MDL value. The

individual MDL value from each laboratory for a given method is used to obtain a median MDL value as a representative inter-laboratory MDL. According to Eaton, et. al. (1993), this inter-laboratory MDL can be multiplied by a factor of 4, 5, or 6 in order to yield a supportable PQL value. Although the Testing Subcommittee chose to use a multiplier of five to determine the PQLs, considering uncertainties around the PQL calculation and lower MCL value proposed for PFOA (1ng/l), we recommend using the lower factor of 4 instead.

Researchers from Harvard University who are investigating PFAS contamination in drinking waters reported a MDL of 0.2 ng/L for PFOA in their recent studies (Zhang et al, 2015).

In order to obtain more representative inter-laboratory MDL value we propose to remove the two unusually highest MDLs (SGS Accutest-Orlando with reported MDL of 8ng/L and Test America-Denver with reported MDL of 9.79 ng/L). The median for the remaining eleven MDLs (0.748 ng/L) multiplied by factor of 4 (0.748 ng/L \times 4 = 2.992), results in a PQL of 3.0.

B. Determination of PQL Using Reporting Limits or Lowest Calibration Standards

The Minimum Reporting Level (MRL) is defined as the minimum concentration by which PFOA is reliably quantitated by the individual laboratory. The Testing Subcommittee also assessed PQL value using the MRLs that account for both accuracy and precision as opposed to MDLs that are mainly a measure of precision.

According to the Testing Subcommittee report, since 2007, laboratories have demonstrated that lower reporting limits are achievable. In fact, NYDEC contracted the services of a laboratory capable of providing a PFOA reporting limit of 2 ng/L. Studies in Southeast Queensland, Australia, reported the Minimum Reporting Levels (MRLs) for PFCs, including PFOA, ranged from 0.4 to 1.5 ng/l (Thompson et al, 2011).

In order to determine a PQL for PFOA based on minimum reporting levels we propose a MRL of 2 ng/L. This is a value that most credible laboratories are currently capable to achieve.

C. Bootstrap Estimate of a Confidence Interval of a Mean

The Testing committee also used an EPA technique called "Bootstrap Estimate of a Confidence Interval of the Mean." This method was applied to generate a normal distribution and associated 95 % upper and lower confidence intervals from the inter-laboratory MDL values and the RLs or the lowest calibration standard. The PQL value of 6.5 ng/L derived from bootstrap analysis of the MDLs multiplied by 5, and the PQL value of 6.0 ng/L derived from the bootstrap analysis of the RLs are both higher the MCL proposed by the authors.

The testing Subcommittee recommended a PQL of 6 ng/L for PFOA to the Drinking Water Quality Institute. This is considerably higher than our proposed MCL of 1 ng/L.

Considering serious adverse health impacts of PFOA, uncertainty inherent in toxicological

studies to develop a protective MCL, and challenges in developing appropriate PQL, the best available control technology for removal of PFOA should be applied in order to protect public health.

Good Afternoon All,

I wanted to get everyone some final estimates and options along with a brief explanation of each, since today is the last day for comments.

Option #1:

This option is an all-encompassing option that includes over 11,700 linear feet of water main. In order for PRA to provide service to this entire area, a booster pump station would need to be installed at the Authority water tank. Although that cost of roughly \$1.3m is included in this estimate, that Authority Board would contribute this cost towards the project to install the pumps and generator.

Option #2:

This option is a slightly slimmed-down project with over 7,100 linear feet of water main. Since there are financial concerns with providing service, this option is a viable option because it is under the \$2m threshold that DEP is legally allowed to spend on the contamination clean-up and this will serve all of the customers with private wells above the 70 PPT HAL. In addition, since the water mains in this option do not extend as far north on Old Bethlehem Pike compared to Option #1, a booster pump is not needed to provide service.

If anyone has any questions or would like a more detailed explanation, please don't hesitate to call or contact me.

Thanks and I hope everyone has a great holiday weekend.

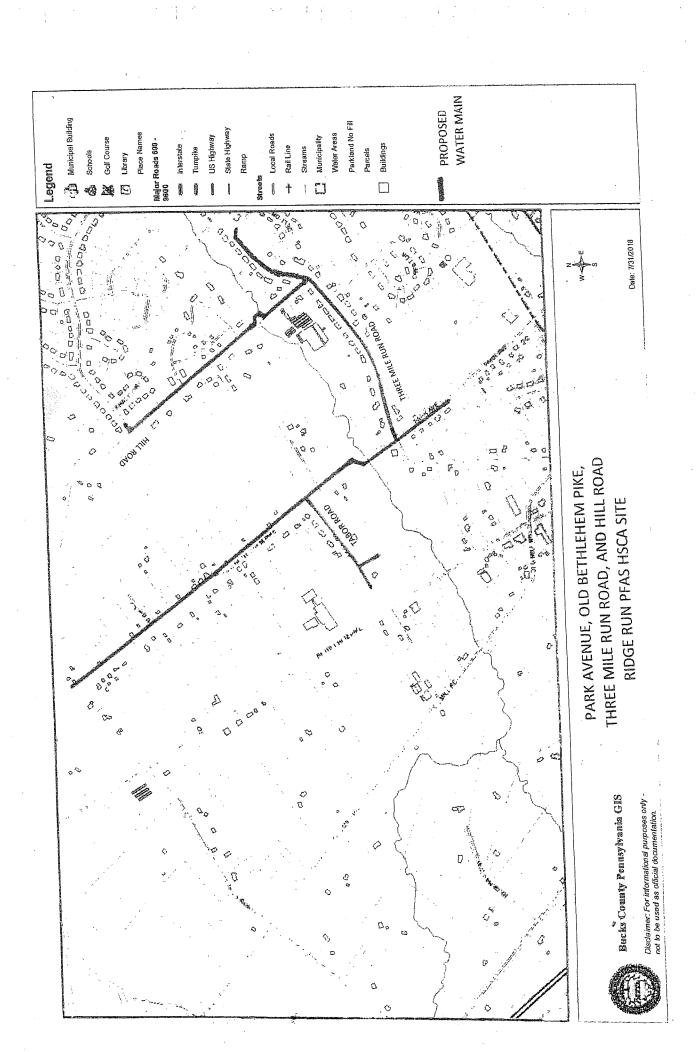

Nick
